Nelson TEXTBOOK *of* PEDIATRICS

EDITION 20

Robert M. Kliegman, MD
Professor and Chair Emeritus
Department of Pediatrics
Medical College of Wisconsin
Milwaukee, Wisconsin

Bonita F. Stanton, MD
Vice-Dean of Research
Professor of Pediatrics
Wayne State University School of Medicine
Detroit, Michigan

Joseph W. St Geme III, MD
Chair, Department of Pediatrics
Professor of Pediatrics and Microbiology
Perelman School of Medicine at the University of Pennsylvania
Physician-in-Chief
Leonard and Madlyn Abramson Endowed Chair in Pediatrics
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Nina F. Schor, MD, PhD
William H. Eilinger Professor and Chair
Department of Pediatrics
Professor
Department of Neurology
Pediatrician-in-Chief
Golisano Children's Hospital
University of Rochester Medical Center
Rochester, New York

Editor Emeritus
Richard E. Behrman, MD
Nonprofit Healthcare and Educational Consultants to Medical Institutions
Santa Barbara, California

NELSON TEXTBOOK OF PEDIATRICS, TWENTIETH EDITION **ISBN: 978-1-4557-7566-8**
International Edition **ISBN: 978-0-323-35307-6**

International Standard Book Number: 978-1-4557-7566-8

Content Strategy Director: Mary Gatsch
Executive Content Strategist: Kate Dimock
Content Development Specialist: Jennifer Shreiner
Publishing Services Manager: Patricia Tannian
Senior Project Manager: John Casey

Printed in Canada

Last digit is the print number: 9 8 7 6 5 4 3 2 1

To the Child's Physician and especially to those who through their expressed confidence in past editions of this book have provided the stimulus for this revision.
Waldo E. Nelson, 9/e, 1969

This is as true in 2015 as it was in 1969.
R.M. Kliegman, 20/e, 2015

Contributors

Mark J. Abzug, MD
Professor of Pediatrics
Division of Pediatric Infectious Diseases
University of Colorado School of Medicine
Children's Hospital Colorado
Aurora, Colorado
Nonpolio Enteroviruses

David R. Adams, MD, PhD
National Human Genome Research Institute
National Institutes of Health
Bethesda, Maryland
Genetic Approaches to Rare and Undiagnosed Diseases

Stewart L. Adelson, MD
Assistant Clinical Professor
Department of Psychiatry
Columbia University College of Physicians and Surgeons
Adjunct Clinical Assistant Professor
Weill Cornell Medical College of Cornell University
New York, New York
Gay, Lesbian, and Bisexual Adolescents

John J. Aiken, MD, FACS, FAAP
Professor of Surgery
Division of Pediatric General and Thoracic Surgery
Medical College of Wisconsin
The Children's Hospital of Wisconsin
Milwaukee, Wisconsin
Acute Appendicitis
Inguinal Hernias
Epigastric Hernia

Begum Akay, MD
Assistant Professor of Surgery
Division of Pediatric Surgery
Oakland University William Beaumont School of Medicine
Beaumont Health
Royal Oak, Michigan
Surgical Conditions of the Anus and Rectum

Cezmi A. Akdis, MD
Professor of Immunology
Swiss Institute of Allergy and Asthma Research
Christine Kühne Center for Allergy Research and Education
Davos, Switzerland;
Medical Faculty, University of Zurich
Zurich, Switzerland
Allergy and the Immunologic Basis of Atopic Disease

Evaline A. Alessandrini, MD, MSCE
Professor of Clinical Pediatrics
University of Cincinnati College of Medicine
Division of Emergency Medicine
Director, Quality Scholars Program in Health Care Transformation
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio
Emergency Medical Services for Children: Outcomes and Risk Adjustment

Michael A. Alexander, MD
Professor of Pediatrics and Rehabilitation Medicine
Thomas Jefferson Medical College
Philadelphia, Pennsylvania;
Emeritus Medical Staff
Alfred I. duPont Hospital for Children
Wilmington, Delaware
Evaluation of the Child for Rehabilitative Services

Omar Ali, MD
Assistant Professor
Department of Pediatrics
Medical College of Wisconsin
Division of Endocrinology
Children's Hospital of Wisconsin
Milwaukee, Wisconsin
Hyperpituitarism, Tall Stature, and Overgrowth Syndromes
Hypofunction of the Testes
Pseudoprecocity Resulting from Tumors of the Testes
Gynecomastia

Namasivayam Ambalavanan, MD
Professor of Pediatrics
Division of Neonatology
University of Alabama, Birmingham
Birmingham, Alabama
High-Risk Pregnancies
The Fetus
Nervous System Disorders
Hypoxia-Ischemic Encephalopathy
Respiratory Tract Disorders
Jaundice and Hyperbilirubinemia in the Newborn
Kernicterus
Genitourinary System
The Umbilicus
Metabolic Disturbances
The Endocrine System

Karl E. Anderson, MD, FACP
Professor
Departments of Preventive Medicine, Community Health, Internal Medicine, and Pharmacology and Toxicology
Director, Porphyria Laboratory and Center
University of Texas Medical Branch
Galveston, Texas
The Porphyrias

Peter M. Anderson, MD, PhD
Curtis Distinguished Professor
Department of Pediatrics
University of Texas MD Anderson Cancer Center
Houston, Texas
Neoplasms of the Kidney

Kelly K. Anthony, PhD, PLLC
Assistant Professor
Department of Psychiatry and Behavioral Sciences
Duke University Medical Center
Durham, North Carolina
Musculoskeletal Pain Syndromes

Alia Y. Antoon, MD
Assistant Clinical Professor
Department of Pediatrics
Harvard Medical School
Chief of Pediatrics
Shriners Hospital for Children
Boston, Massachusetts
Burn Injuries
Cold Injuries

Susan D. Apkon, MD
Associate Professor
Department of Rehabilitation Medicine
University of Washington School of Medicine
Director, Rehabilitation Medicine
Seattle Children's Hospital
Seattle, Washington
Ambulation Assistance

Stacy P. Ardoin, MD, MHS
Associate Professor of Clinical Medicine
Adult and Pediatric Rheumatology
The Ohio State University Wexner Medical Center
Nationwide Children's Hospital
Columbus, Ohio
Systemic Lupus Erythematosus
Vasculitis Syndromes

Monica I. Ardura, DO, MSCS
Assistant Professor of Pediatrics
Section of Infectious Disease and Immunology
The Ohio State University College of Medicine
Nationwide Children's Hospital
Columbus, Ohio
Hansen Disease (Mycobacterium leprae)

Michelle M. Ariss, MD
Assistant Professor
Department of Ophthalmology
University of Missouri—Kansas City School of Medicine
Children's Mercy Hospital
Kansas City, Missouri
Growth and Development (Eye)
Examination of the Eye
Abnormalities of Refraction and Accommodation
Disorders of Vision
Abnormalities of Pupil and Iris
Disorders of Eye Movement and Alignment
Abnormalities of the Lids
Disorders of the Lacrimal System
Disorders of the Conjunctiva
Abnormalities of the Cornea
Abnormalities of the Lens
Disorders of the Uveal Tract
Disorders of the Retina and Vitreous
Abnormalities of the Optic Nerve
Childhood Glaucoma
Orbital Abnormalities
Orbital Infections
Injuries to the Eye

Thaís Armangué, MD
Clinical Fellow and Predoctoral Researcher
ICREA-IDIBAPS Neuroimmunology Program
Hospital Clinic
Barcelona, Spain
Autoimmune Encephalitis

Carola A.S. Arndt, MD
Professor of Pediatrics
Department of Pediatrics and Adolescent Medicine
Division of Pediatric Hematology-Oncology
Mayo Clinic
Rochester, Minnesota
Soft Tissue Sarcomas
Neoplasms of Bone

Stephen S. Arnon, MD, MPH
Chief, Infant Botulism Treatment and Prevention Program Branch
Division of Communicable Disease Control
Center for Infectious Diseases
California Department of Public Health
Richmond, California
Botulism (Clostridium botulinum)
Tetanus (Clostridium tetani)

Stephen C. Aronoff, MD, MBA
Professor and Waldo E. Nelson Chair
Department of Pediatrics
Temple University School of Medicine
Philadelphia, Pennsylvania
Cryptococcus neoformans
Histoplasmosis (Histoplasma capsulatum)
Paracoccidioides brasiliensis
Sporotrichosis (Sporothrix schenckii)
Zygomycosis (Mucormycosis)
Nonbacterial Food Poisoning

David M. Asher, MD
Supervisory Medical Officer
Chief, Laboratory of Bacterial and Transmissible Spongiform Encephalopathy Agents
Center for Biologics Evaluation and Research (CBER)
United States Food and Drug Administration
Silver Spring, Maryland
Transmissible Spongiform Encephalopathies

Ann Ashworth, PhD, Hon FRCPCH
Professor Emeritus
Department of Population Health
Nutrition Group
London School of Hygiene and Tropical Medicine
London, United Kingdom
Nutrition, Food Security, and Health

Barbara L. Asselin, MD
Professor of Pediatrics and Oncology
Department of Pediatrics
University of Rochester School of Medicine
Golisano Children's Hospital
Rochester, New York
Epidemiology of Childhood and Adolescent Cancer

Joann L. Ater, MD
Associate Professor
Department of Pediatrics
University of Texas MD Anderson Cancer Center
Houston, Texas
Brain Tumors in Childhood
Neuroblastoma

Erika F. Augustine, MD
Assistant Professor of Neurology and Pediatrics
Division of Child Neurology
University of Rochester Medical Center
Rochester, New York
Dystonia

Marilyn C. Augustyn, MD
Professor of Pediatrics
Boston University School of Medicine
Boston Medical Center
Boston, Massachusetts
Impact of Violence on Children

Ellis D. Avner, MD
Professor
Departments of Pediatrics and Physiology
Medical College of Wisconsin
Milwaukee, Wisconsin
Introduction to Glomerular Diseases
Clinical Evaluation of the Child with Hematuria
Isolated Glomerular Diseases with Recurrent Gross Hematuria
Glomerulonephritis Associated with Infections
Membranous Nephropathy
Membranoproliferative Glomerulonephritis
Glomerulonephritis Associated with Systemic Lupus Erythematosus
Henoch-Schönlein Purpura Nephritis
Rapidly Progressive (Crescentic) Glomerulonephritis
Goodpasture Disease
Hemolytic-Uremic Syndrome
Upper Urinary Tract Causes of Hematuria
Hematologic Diseases Causing Hematuria
Anatomic Abnormalities Associated with Hematuria
Lower Urinary Tract Causes of Hematuria
Introduction to the Child with Proteinuria
Transient Proteinuria
Orthostatic (Postural) Proteinuria
Fixed Proteinuria
Nephrotic Syndrome
Tubular Function
Renal Tubular Acidosis
Nephrogenic Diabetes Insipidus
Bartter and Gitelman Syndromes and Other Inherited Tubular Transport Abnormalities
Tubulointerstitial Nephritis
Toxic Nephropathy
Cortical Necrosis
Renal Failure

Carlos A. Bacino, MD
Professor of Molecular and Human Genetics
Baylor College of Medicine
Chief, Genetics Service
Director, Pediatric Genetics Clinic
Texas Children's Hospital
Houston, Texas
Cytogenetics

Robert N. Baldassano, MD
Colman Family Chair in Pediatric Inflammatory Bowel Disease and Professor of Pediatrics
University of Pennsylvania Perelman School of Medicine
Director, Center for Pediatric Inflammatory Bowel Disease
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania
Inflammatory Bowel Disease
Eosinophilic Gastroenteritis

Keith D. Baldwin, MD, MSPT, MPH

Human Metapneumovirus

Steve J. Czinn, MD
Professor and Chair
Department of Pediatrics
University of Maryland School of Medicine
Baltimore, Maryland
Peptic Ulcer Disease in Children

Josep O. Dalmau, MD, PhD
Research Professor ICREA-IDIBAPS
Department of Neurology
Hospital Clinic
Barcelona, Spain;
Adjunct Professor of Neurology
University of Pennsylvania Perelman School of Medicine
Philadelphia, Pennsylvania
Autoimmune Encephalitis

Toni Darville, MD
Professor of Pediatrics and Microbiology and Immunology
University of North Carolina at Chapel Hill School of Medicine
Vice-Chair for Pediatric Research
Chief, Division of Pediatric Infectious Diseases
NC Children's Hospital
Chapel Hill, North Carolina
Neisseria gonorrhoeae (*Gonococcus*)

Robert S. Daum, MD, CM
Professor of Pediatrics, Microbiology, and Molecular Medicine
University of Chicago Pritzker School of Medicine
Department of Pediatric Infectious Diseases
The University of Chicago Medicine Comer Children's Hospital
Chicago, Illinois
Haemophilus influenzae

Loren T. Davidson, MD
Assistant Clinical Professor
Department of Physical Medicine and Rehabilitation
University of California, Davis
Davis, California;
Director, Spinal Cord Injury
Shriner's Hospital for Children
Sacramento, California
Spasticity

Richard S. Davidson, MD
Clinical Professor
Department of Orthopaedic Surgery
University of Pennsylvania Perelman School of Medicine
Attending Orthopaedic Surgeon
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania
The Foot and Toes
Leg-Length Discrepancy
Arthrogryposis

H. Dele Davies, MD, MS, MHCM
Vice-Chancellor for Academic Affairs
Dean for Graduate Studies
University of Nebraska Medical Center
Omaha, Nebraska
Chancroid (Haemophilus ducreyi)
Syphilis (Treponema pallidum)
Nonvenereal Treponemal Infections
Leptospira
Relapsing Fever (Borrelia)

Najat C. Daw, MD
Professor
Division of Pediatrics
University of Texas MD Anderson Cancer Center
Houston, Texas
Neoplasms of the Kidney

Peter S. Dayan, MD
Assistant Professor of Clinical Pediatrics
Columbia University College of Physicians and Surgeons
Associate Director and Fellowship Director
Division of Pediatric Emergency Medicine
Morgan Stanley Children's Hospital of New York–Presbyterian
New York, New York
Acute Care of the Victim of Multiple Trauma

Michael R. DeBaun, MD, MPH
Professor of Pediatrics and Medicine
J.C. Peterson Chair in Pediatric Pulmonology
Vice-Chair for Clinical Research
Pediatrics Director, Vanderbilt-Maherry Center of Excellence in Sickle Cell Disease
Vanderbilt University
Nashville, Tennessee
Hemoglobinopathies

David R. DeMaso, MD
George P. Gardner and Olga E. Monks Professor of Child Psychiatry
Professor of Pediatrics
Harvard Medical School
Psychiatrist-in-Chief and Chairman of Psychiatry
The Leon Eisenberg Chair in Psychiatry
Boston Children's Hospital
Boston, Massachusetts
Assessment and Interviewing
Psychological Treatment of Children and Adolescents
Psychopharmacology
Psychotherapy
Psychiatric Hospitalization
Somatic Symptom and Related Disorders
Rumination and Pica
Motor Disorders and Habits
Mood Disorders
Suicide and Attempted Suicide
Disruptive, Impulse-Control, and Conduct Disorders
Autism Spectrum Disorder
Childhood Psychoses

Mark R. Denison, MD
Craig-Weaver Professor of Pediatrics
Division of Pediatric Infectious Disease
Vanderbilt University Medical Center
Nashville, Tennessee
Coronaviruses

Arlene E. Dent, MD, PhD
Assistant Professor of Pediatrics
Division of Infectious Diseases
Case Western Reserve University School of Medicine
Cleveland, Ohio
Ascariasis (Ascaris lumbricoides)
Trichuriasis (Trichuris trichiura)
Enterobiasis (Enterobius vermicularis)
Strongyloidiasis (Strongyloides stercoralis)
Lymphatic Filariasis (Brugia malayi, Brugia timori, *and* Wuchereria bancrofti)
Other Tissue Nematodes
Toxocariasis (Visceral and Ocular Larva Migrans)
Trichinosis (Trichinella spiralis)

Robert J. Desnick, MD, PhD
Dean for Genetics and Genomic Medicine
Professor and Chair Emeritus, Genetics and Genomic Sciences
Professor, Departments of Pediatrics, Oncological Sciences, and Obstetrics, Gynecology, and Reproductive Science
Icahn School of Medicine at Mount Sinai
New York, New York
Lipidoses (Lysosomal Storage Disorders)
Mucolipidoses
Disorders of Glycoprotein Degradation and Structure
The Porphyrias

Gabrielle A. deVeber, MD, MHSc
Professor of Paediatrics
Director, Children's Stroke Program
University of Toronto Faculty of Medicine
Staff Neurologist
Senior Scientist, Child Health Evaluative Sciences
The Hospital for Sick Children
Toronto, Ontario, Canada
Pediatric Stroke

Anil Dhawan, MD
Consultant Paediatric Hepatologist
Pediatric Liver Centre
King's College London School of Medicine
King's College Hospital NSH Foundation Trust
London, United Kingdom
Liver and Biliary Disorders Causing Malabsorption

André A.S. Dick, MD, MPH, FACS
Assistant Professor of Surgery
Division of Transplantation
University of Washington School of Medicine
Division of Transplant Surgery
Seattle Children's Hospital
Seattle, Washington
Intestinal Transplantation in Children with Intestinal Failure

Brianne Z. Dickey, MD
Resident Physician
Department of Dermatology
Medical College of Wisconsin
Milwaukee, Wisconsin
Morphology of the Skin
Evaluation of the Patient
Eczematous Disorders
Photosensitivity
Diseases of the Epidermis

Harry C. Dietz III, MD
Victor A. McKusick Professor of Medicine and Genetics
Departments of Pediatrics, Medicine, and Molecular Biology and Genetics
Investigator, Howard Hughes Medical Institute
Director, William S. Smilow Center for Marfan Syndrome Research
Institute of Genetic Medicine
Johns Hopkins University School of Medicine
Baltimore, Maryland
Marfan Syndrome

Lydia J. Donoghue, MD
Director, Trauma Center
Children's Hospital of Michigan
Detroit, Michigan
Tumors of the Digestive Tract

Johns Hopkins University School of Medicine
Baltimore, Maryland
Marfan Syndrome

Patrick C. Drayna, MD
Assistant Professor of Pediatrics
Division of Pediatric Emergency Medicine
Medical College of Wisconsin
Children's Hospital of Wisconsin
Milwaukee, Wisconsin
Evaluation of the Sick Child in the Office and Clinic

Stephen C. Dreskin, MD, PhD
Professor of Medicine and Immunology
Division of Allergy and Clinical Immunology
Department of Medicine
University of Colorado School of Medicine
Aurora, Colorado
Urticaria (Hives) and Angioedema

Beth A. Drolet, MD
Professor of Dermatology
Medical College of Wisconsin
Children's Hospital of Wisconsin
Milwaukee, Wisconsin
Principles of Therapy (Skin)
Hyperpigmented Lesions
Diseases of Subcutaneous Tissue
Disorders of the Mucous Membranes
Cutaneous Bacterial Infections
Cutaneous Fungal Infections
Cutaneous Viral Infections
Arthropod Bites and Infestations

Yigal Dror, MD, FRCP(C)
Professor of Paediatrics
University of Toronto Faculty of Medicine
Head, Hematology Section Director, Marrow Failure and Myelodysplasia Program
The Hospital for Sick Children
Toronto, Ontario, Canada
The Inherited Pancytopenias

Howard Dubowitz, MD, MS, FAAP
Professor of Pediatrics
Chief, Division of Child Protection
Director, Center for Families
Department of Pediatrics
University of Maryland School of Medicine
Baltimore, Maryland
Abused and Neglected Children

J. Stephen Dumler, MD
Professor of Pathology and Microbiology and Immunology
University of Maryland School of Medicine
Baltimore, Maryland
Spotted Fever Group Rickettsioses
Scrub Typhus (Orientia tsutsugamushi)
Typhus Group Rickettsioses
Ehrlichioses and Anaplasmosis
Q Fever (Coxiella burnetii)

Aubrey N. Duncan, MD
Resident Physician
Department of Pediatrics
University of Rochester Medical Center
Rochester, New York
Deformational Plagiocephaly

Janet Duncan, MSN, CPNP
Department of Psychosocial Oncology and Palliative Care
Boston Children's Hospital
Dana-Farber Cancer Institute
Boston, Massachusetts
Pediatric Palliative Care

Paula M. Duncan, MD
Professor
Department of Pediatrics
University of Vermont College of Medicine
Burlington, Vermont
Maximizing Children's Health: Screening, Anticipatory Guidance, and Counseling

Jeffrey A. Dvergsten, MD
Assistant Professor of Pediatrics
Duke University School of Medicine
Division of Pediatric Rheumatology
Duke University Health System
Durham, North Carolina
Treatment of Rheumatic Diseases

Michael G. Earing, MD
Professor of Internal Medicine and Pediatrics
Division of Adult Cardiovascular Medicine and Division of Pediatric Cardiology
Medical College of Wisconsin
Director, Wisconsin Adult Congenital Heart Disease Program (WAtCH)
Children's Hospital of Wisconsin
Milwaukee, Wisconsin
Congenital Heart Disease in Adults

Matthew D. Eberly, MD
Assistant Professor of Pediatrics
Uniformed Services University of the Health Sciences
Bethesda, Maryland
Primary Amebic Meningoencephalitis

Elizabeth A. Edgerton, MD, MPH
Assistant Professor
Departments of Pediatrics and Preventive and Community Health
George Washington University School of Medicine
Division of Emergency Medicine
Children's National Medical Center
Washington, DC
Interfacility Transport of the Seriously Ill or Injured Pediatric Patient

Marie E. Egan, MD
Associate Professor of Pediatrics (Respiratory) and of Cellular and Molecular Physiology
Director, Cystic Fibrosis Center
Yale School of Medicine
New Haven, Connecticut
Cystic Fibrosis

Chief of Pediatric Urology
Massachusetts General Hospital
Boston, Massachusetts
Congenital Anomalies and Dysgenesis of the Kidneys
Urinary Tract Infections
Vesicoureteral Reflux
Obstruction of the Urinary Tract
Anomalies of the Bladder
Neuropathic Bladder
Enuresis and Voiding Dysfunction
Anomalies of the Penis and Urethra
Disorders and Anomalies of the Scrotal Contents
Trauma to the Genitourinary Tract
Urinary Lithiasis

Dianne S. Elfenbein, MD
Professor of Pediatrics
Director, Division of Adolescent Medicine
St. Louis University School of Medicine
St. Louis, Missouri
Adolescent Pregnancy

Stephen C. Eppes, MD, FAAP
Professor of Pediatrics
Jefferson Medical College of Thomas Jefferson University
Philadelphia, Pennsylvania;
Director, Pediatric Infectious Diseases
Christiana Care Health System
Wilmington, Delaware
Lyme Disease (Borrelia burgdorferi)

Jessica Ericson, MD
Pediatric Infectious Diseases Fellow
Duke University Medical Center
Durham, North Carolina
Candida

Alessio Fasano, MD
Visiting Professor of Pediatrics
Harvard Medical School
Chief, Division of Pediatric Gastroenterology and Nutrition
Associate Chief, Department of Pediatrics, Basic, Clinical, and Translational Research
Director, Center for Celiac Research
MassGeneral Hospital for Children
Boston, Massachusetts
Celiac Disease (Gluten-Sensitive Enteropathy)

Susan Feigelman, MD
Professor, Department of Pediatrics
University of Maryland School of Medicine
Baltimore, Maryland
Overview and Assessment of Variability
Assessment of Fetal Growth and Development
The First Year
The Second Year
The Preschool Years
Middle Childhood

Marianne E. Felice, MD
Professor
Departments of Pediatrics and Obstetrics and Gynecology
University of Massachusetts Medical School
Principle Investigator, National Children's Study
UMass Study Center
Worcester, Massachusetts
Adolescent Pregnancy
Adolescent Rape

Eric I. Felner, MD, MSCR
Associate Professor of Pediatrics
Division of Pediatric Endocrinology
Director, Pediatric Endocrinology Fellowship Program
Director, Pediatric Clerkships
Emory University School of Medicine
Atlanta, Georgia
Hormones of the Hypothalamus and Pituitary
Hypopituitarism

Edward C. Fels, MD
Pediatric and Adult Rheumatology
Rheumatology Associates, PA
Portland, Maine
Vasculitis Syndromes

Kora N. Felsch, MD
Hospitalist
Cardinal Glennon Children's Medical Center
St. Louis, Missouri
Breast Concerns

Thomas W. Ferkol Jr., MD
Alexis Hartmann Professor of Pediatrics
Director, Division of Pediatric Allergy, Immunology, and Pulmonary Medicine
Washington University School of Medicine in St. Louis
St. Louis, Missouri
Primary Ciliary Dyskinesia (Immotile Cilia Syndrome, Kartagener Syndrome)

Can H. Ficicioglu, MD, PhD
Associate Professor
Department of Pediatrics
University of Pennsylvania Perelman School of Medicine
Director, Newborn Metabolic Screening Program
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania
Phenylalanine

Jonathan D. Finder, MD
Professor of Pediatrics
University of Pittsburgh School of Medicine
Attending Pediatric Pulmonologist
Division of Pediatric Pulmonology
Children's Hospital of Pittsburgh of UPMC
Pittsburgh, Pennsylvania
Bronchomalacia and Tracheomalacia
Congenital Disorders of the Lung

Kristin N. Fiorino, MD
Assistant Professor of Clinical Pediatrics
University of Pennsylvania Perelman School of Medicine
Attending Physician
Division of Gastroenterology, Hepatology, and Nutrition
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania
Motility Disorders and Hirschsprung Disease

Philip R. Fischer, MD
Professor of Pediatrics
Mayo Clinic
Rochester, Minnesota
Adult Tapeworm Infections
Cysticercosis
Echinococcosis (Echinococcus granulosus *and* Echinococcus multilocularis)

Veronica H. Flood, MD
Associate Professor of Pediatrics
Division of Pediatric Hematology/Oncology
Medical College of Wisconsin
Milwaukee, Wisconsin
Hereditary Clotting Factor Deficiencies (Bleeding Disorders)
von Willebrand Disease
Thrombocytopenia from Acquired Disorders Causing Decreased Production

Patricia M. Flynn, MD
Deputy Clinical Director
Arthur Ashe Chair in Pediatric AIDS Research
Director, Clinical Research, Infectious Diseases
St. Jude Children's Research Hospital
Professor of Pediatrics and Preventive Medicine
University of Tennessee College of Medicine
Memphis, Tennessee
Infection Associated with Medical Devices
Cryptosporidium, Isospora, Cyclospora, *and Microsporidia*

Joel A. Forman, MD
Associate Professor of Pediatrics and Preventive Medicine
Vice-Chair for Education
Department of Pediatrics
Icahn School of Medicine at Mount Sinai
New York, New York
Chemical Pollutants

Michael M. Frank, MD
Samuel L. Katz Professor of Pediatrics, Medicine, and Immunology
Duke University School of Medicine
Durham, North Carolina
Urticaria (Hives) and Angioedema

Melvin H. Freedman, MD, FRCP(C), FAAP
Professor Emeritus of Pediatrics
University of Toronto Faculty of Medicine
Honorary Consultant, Hematology/Oncology
The Hospital for Sick Children
Toronto, Ontario, Canada
The Inherited Pancytopenias

Megan Culler Freeman, PhD
Departments of Pediatrics and Pathology, Microbiology, and Immunology
Vanderbilt University School of Medicine
Nashville, Tennessee
Coronaviruses

Melissa J. Frei-Jones, MD, MSCI
Assistant Professor of Pediatrics
Division of Pediatric Hematology/Oncology
University of Texas Health Sciences Center
Santa Rosa Children's Hospital
San Antonio, Texas
Hemoglobinopathies

Deborah Friedman, MD
Assistant Clinical Professor of Pediatrics
Case Western Reserve University School of Medicine
Cleveland, Ohio
Neonatal Lupus

Erika Friehling, MD
Assistant Professor of Pediatrics
University of Pittsburgh School of Medicine
Division of Pediatric Hematology/Oncology
Children's Hospital of Pittsburgh of UPMC
Pittsburgh, Pennsylvania
Principles of Diagnosis (Cancer and Benign Tumors)
Principles of Treatment (Cancer and Benign Tumors)
The Leukemias

Donald P. Frush, MD
Professor of Radiology
Chief, Division of Pediatric Radiology
Duke University Medical Center

Attending Physician
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania
Arthrogryposis

William A. Horton, MD
Professor
Department of Molecular Medical Genetics
Oregon Health & Science University
Director of Research
Shriners Hospitals for Children
Portland, Oregon
General Considerations (Bone and Joint Disorders)
Disorders Involving Cartilage Matrix Proteins
Disorders Involving Transmembrane Receptors
Disorders Involving Ion Transporters
Disorders Involving Transcription Factors
Disorders Involving Defective Bone Resorption
Disorders for Which Defects Are Poorly Understood or Unknown

Peter J. Hotez, MD, PhD, FASTMH, FAAP
Founding Dean, National School of Tropical Medicine
Professor of Pediatrics and Molecular Virology and Microbiology
Baylor College of Medicine
Endowed Chair in Tropical Pediatrics
Texas Children's Hospital
Houston, Texas
Hookworms (Necator americanus *and* Ancylostoma *spp.)*

Evelyn Hsu, MD
Assistant Professor of Pediatrics
Seattle Children's Hospital
Seattle, Washington
Liver Transplantation

Stephen A. Huang, MD
Assistant Professor of Pediatrics
Harvard Medical School
Director, Thyroid Program
Division of Endocrinology
Boston Children's Hospital
Boston, Massachusetts
Thyroid Development and Physiology
Defects of Thyroxine-Binding Globulin
Hypothyroidism
Thyroiditis
Goiter
Hyperthyroidism
Carcinoma of the Thyroid

Heather G. Huddleston, MD
Assistant Professor
Department of Obstetrics, Gynecology, and Reproductive Sciences
University of California, San Francisco School of Medicine
San Francisco, California
Polycystic Ovary Syndrome and Hirsutism

Vicki Huff, PhD
Professor
Department of Molecular Genetics/Cancer Genetics
University of Texas MD Anderson Cancer Center
Houston, Texas
Neoplasms of the Kidney

Denise Hug, MD
Associate Professor
Department of Ophthalmology
University of Missouri—Kansas City School of Medicine
Children's Mercy Hospital
Kansas City, Missouri
Growth and Development (Eye)
Examination of the Eye
Abnormalities of Refraction and Accommodation
Disorders of Vision
Abnormalities of Pupil and Iris
Disorders of Eye Movement and Alignment
Abnormalities of the Lids
Disorders of the Lacrimal System
Disorders of the Conjunctiva
Abnormalities of the Cornea
Abnormalities of the Lens
Disorders of the Uveal Tract
Disorders of the Retina and Vitreous
Abnormalities of the Optic Nerve
Childhood Glaucoma
Orbital Abnormalities
Orbital Infections
Injuries to the Eye

Dennis P.M. Hughes, MD, PhD
Associate Professor of Pediatrics
University of Texas MD Anderson Cancer Center
Houston, Texas
Melanoma

Winston W. Huh, MD
Assistant Professor of Pediatrics
University of Texas MD Anderson Cancer Center
Houston, Texas
Gonadal and Germ Cell Neoplasms
Adenocarcinoma of the Colon and Rectum

Stephen R. Humphrey, MD
Resident Physician
Department of Dermatology
Medical College of Wisconsin
Children's Hospital of Wisconsin
Milwaukee, Wisconsin
Principles of Therapy (Skin)

David A. Hunstad, MD
Associate Professor of Pediatrics and Molecular Microbiology
Washington University School of Medicine in St. Louis
St. Louis, Missouri
Animal and Human Bites

Carl E. Hunt, MD
Research Professor of Pediatrics
Uniformed Services University of the Health Sciences
Division of Neonatology
Walter Reed National Military Medical Center
Bethesda, Maryland;
Adjunct Professor of Pediatrics
George Washington University School of Medicine
Washington, DC
Sudden Infant Death Syndrome

Anna K. Hunter, MD
Assistant Clinical Professor of Pediatrics
University of California, San Francisco
UCSF Fresno Center for Medical Education and Research
Fresno, California;
Pediatric Gastroenterologist
Children's Hospital Central California
Madera, California
Pyloric Stenosis and Other Congenital Anomalies of the Stomach

Stacey S. Huppert, PhD
Associate Professor of Pediatrics
University of Cincinnati College of Medicine
Division of Gastroenterology, Hepatology, and Nutrition
Division of Developmental Biology
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio
Morphogenesis of the Liver and Biliary System

Patricia I. Ibeziako, MD
Assistant Professor of Psychiatry
Harvard Medical School
Director, Psychiatry Consultation Service
Boston Children's Hospital
Boston, Massachusetts
Somatic Symptom and Related Disorders

Samar H. Ibrahim, MBChB
Assistant Professor of Pediatrics
Division of Pediatric Gastroenterology and Hepatology
Mayo Clinic
Rochester, Minnesota
Mitochondrial Hepatopathies

Richard F. Jacobs, MD, FAAP
Robert H. Fiser Jr. MD Endowed Chair in Pediatrics
Professor and Chair, Department of Pediatrics
University of Arkansas for Medical Sciences
Pediatrician-in-Chief
Arkansas Children's Hospital
Little Rock, Arkansas
Actinomyces
Nocardia
Tularemia (Francisella tularensis)
Brucella

Tara Jatlaoui, MD, MPH
Research Assistant Professor
Department of Obstetrics and Gynecology
The University of North Carolina at Chapel Hill
Guest Researcher, Division of Reproductive Health
Centers for Disease Control and Prevention
Atlanta, Georgia
Contraception

M. Kyle Jensen, MD
Assistant Professor of Pediatrics
University of Utah School of Medicine
Division of Pediatric Gastroenterology
Primary Children's Hospital
Salt Lake City, Utah
Viral Hepatitis

Hal B. Jenson, MD, MBA
Founding Dean
Professor, Department of Pediatric and Adolescent Medicine
Western Michigan University
Homer Stryker M.D. School of Medicine
Kalamazoo, Michigan
Chronic Fatigue Syndrome
Epstein-Barr Virus
Human T-Lymphotropic Viruses (1 and 2)

Chandy C. John, MD, MS
Ryan White Professor of Pediatrics
Professor of Pediatrics, Microbiology and Immunology
Director, Ryan White Center for Pediatric Infectious Diseases and Global Health
Indiana University School of Medicine
Riley Hospital for Children at Indiana University Health
Indianapolis, Indiana
Health Advice for Children Traveling Internationally
Giardiasis and Balantidiasis
Malaria (Plasmodium)

Collin C. John, MD, MPH, FAAP
Assistant Professor of Internal Medicine and Pediatrics
Medical Director, West Virginia Birth Score Program
West Virginia University School of Medicine
Morgantown, West Virginia
Disorders of Lipoprotein Metabolism and Transport

Michael V. Johnston, MD
Professor of Neurology, Pediatrics, and Physical Medicine and Rehabilitation
Johns Hopkins University School of Medicine
Kennedy Krieger Institute
Baltimore, Maryland
Congenital Anomalies of the Central Nervous System
Encephalopathies

Richard B. Johnston Jr., MD
Professor of Pediatrics
Associate Dean for Research Development
University of Colorado School of Medicine
Aurora, Colorado;
National Jewish Health
Denver, Colorado
Monocytes, Macrophages, and Dendritic Cells
The Complement System
Disorders of the Complement System

Bridgette L. Jones, MD
Associate Professor of Pediatrics
Division of Allergy, Asthma, and Immunology
University of Missouri—Kansas City School of Medicine
Section of Clinical Pharmacology and Medical Toxicology
Children's Mercy Hospitals and Clinics
Kansas City, Missouri
Principles of Drug Therapy

James F. Jones, MD
Research Medical Officer
Viral Exanthems and Herpesvirus Branch
Division of Viral and Rickettsial Diseases
National Center for Infectious Diseases
Centers for Disease Control and Prevention
Atlanta, Georgia
Chronic Fatigue Syndrome

Marsha Joselow, MSW, LICSW
Department of Psychosocial Oncology and Palliative Care
Boston Children's Hospital
Dana-Farber Cancer Institute
Boston, Massachusetts
Pediatric Palliative Care

Nicholas Jospe, MD
Professor of Pediatrics
Division of Pediatric Endocrinology
Golisano Children's Hospital
University of Rochester Medical Center
Rochester, New York
Diabetes Mellitus

Joel C. Joyce, MD
Pediatric Dermatology
NorthShore University HealthSystem
Skokie, Illinois;
Clinician Educator
University of Chicago Pritzker School of Medicine
Chicago, Illinois
Vesiculobullous Disorders
Nutritional Dermatoses

Anna M. Juern, MD
Division of Pediatric Dermatology
Medical College of Wisconsin
Milwaukee, Wisconsin
Hyperpigmented Lesions
Cutaneous Bacterial Infections
Cutaneous Fungal Infections
Cutaneous Viral Infections
Arthropod Bites and Infestations

Marielle A. Kabbouche, MD
Associate Professor of Pediatrics and Neurology
University of Cincinnati College of Medicine
Division of Neurology
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio
Headaches

Linda Kaljee, PhD, MAA
Associate Professor
Department of Pediatrics
Prevention Research Center
Wayne State University School of Medicine
Detroit, Michigan
Cultural Issues in Pediatric Care

Deepak Kamat, MD, PhD, FAAP
Professor and Vice-Chair of Education
Department of Pediatrics
Wayne State University School of Medicine
Designated Institutional Official
Children's Hospital of Michigan
Detroit, Michigan
Fever
Fever Without a Focus

Alvina R. Kansra, MD
Assistant Professor of Pediatrics
Medical College of Wisconsin
Division of Endocrinology
Children's Hospital of Wisconsin
Milwaukee, Wisconsin
Hypofunction of the Ovaries
Pseudoprecocity Resulting from Lesions of the Ovary

Sheldon L. Kaplan, MD
Professor and Vice-Chair for Clinical Affairs
Department of Pediatrics
Baylor College of Medicine
Head, Department of Pediatric Medicine
Chief, Section of Infectious Disease
Texas Children's Hospital
Houston, Texas
Osteomyelitis
Septic Arthritis

Aaron M. Karlin, MD
Clinical Associate Professor
Department of Physical Medicine and Rehabilitation
Louisiana State University School of Medicine
Section Head, Pediatric Rehabilitation
Ochsner Clinic Medical Center
Ochsner Children's Health Center
New Orleans, Louisiana
Management of Musculoskeletal Injury
Specific Sports and Associated Injuries

Daniel L. Kastner, MD, PhD
Scientific Director
National Human Genome Research Institute
Distinguished Investigator
Medical Genetics Branch
National Institutes of Health
Bethesda, Maryland
Hereditary Periodic Fever Syndromes and Other Systemic Autoinflammatory Diseases

Emily R. Katz, MD
Clinical Assistant Professor
Department of Psychiatry and Human Behavior
Brown University Alpert Medical School
Director, Consultation Liaison Service
Hasbro Children's Hospital
Providence, Rhode Island
Rumination and Pica

James W. Kazura, MD
Professor of Medicine in International Health
Division of Geographic Medicine
Case Western Reserve University School of Medicine
Cleveland, Ohio
Ascariasis (Ascaris lumbricoides)
Trichuriasis (Trichuris trichiura)
Enterobiasis (Enterobius vermicularis)
Strongyloidiasis (Strongyloides stercoralis)
Lymphatic Filariasis (Brugia malayi, Brugia timori, *and* Wuchereria bancrofti)
Other Tissue Nematodes
Toxocariasis (Visceral and Ocular Larva Migrans)
Trichinosis (Trichinella spiralis)

Virginia A. Keane, MD
Associate Professor
Department of Pediatrics
University of Maryland School of Medicine
Baltimore, Maryland
Assessment of Growth

Gregory L. Kearns, PharmD, PhD
Marion Merrell Dow / Missouri Chair of Medical Research
Professor of Pediatrics and Pharmacology
University of Missouri—Kansas City School of Medicine
Chief Scientific Officer and Chairman, Research Development and Clinical Investigation
Associate Chair, Department of Pediatrics
Director, Pediatric Trial Network
Children's Mercy Hospitals and Clinics
Kansas City, Missouri;
Clinical Professor of Pediatrics
University of Kansas School of Medicine
Kansas City, Kansas
Principles of Drug Therapy

Sarah E. Keesecker, MD
Postdoctoral Residency Fellow
Department of Otolaryngology—Head and Neck Surgery
Columbia University College of Physicians and Surgeons
New York, New York
Congenital Disorders of the Nose
Acquired Disorders of the Nose
Nasal Polyps
General Considerations and Evaluation (Ear)
Hearing Loss
Congenital Malformations
External Otitis (Otitis Externa)
The Inner Ear and Diseases of the Bony Labyrinth
Traumatic Injuries of the Ear and Temporal Bone
Tumors of the Ear and Temporal Bone

Desmond P. Kelly, MD
Professor of Clinical Pediatrics
Vice-Chair for Academics, Department of Pediatrics
University of South Carolina School of Medicine Greenville
Greenville, South Carolina
Neurodevelopmental Function and Dysfunction in the School-Age Child

Kevin J. Kelly, MD
Professor of Pediatrics
Division of Pediatric Allergy, Immunology, and Rheumatology
University of North Carolina School of Medicine
Vice-Chair, Clinical Operations
Pediatrician-in-Chief
North Carolina Children's Hospital
Chapel Hill, North Carolina
Immune and Inflammatory Lung Disease

Matthew S. Kelly, MD, MPH
Pediatric Global Health Fellow
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania;
Princess Marina Hospital
Gaborone, Botswana, Africa
Community-Acquired Pneumonia

Judith R. Kelsen, MD
Assistant Professor of Pediatrics
University of Pennsylvania Perelman School of Medicine
Attending Physician
Division of Gastroenterology, Hepatology, and Nutrition
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania
Foreign Bodies and Bezoars

Kathi J. Kemper, MD, MPH
Director, OSU Center for Integrative Health and Wellness
Professor of Pediatrics, Nursing, and Health and Rehabilitation Sciences
Ohio State University Wexner Medical Center
Nationwide Children's Hospital
Columbus, Ohio
Complementary Therapies and Integrative Medicine

Melissa Kennedy, MD
Attending Physician
Division of Gastroenterology, Hepatology, and Nutrition
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania
Malrotation
Meckel Diverticulum and Other Remnants of the Omphalomesenteric Duct
Intussusception
Malformations
Ascites

Eitan Kerem, MD
Professor and Chair
Department of Pediatrics
Hadassah University Medical Center
Jerusalem, Israel
Effects of War on Children

Joseph E. Kerschner, MD, FACS, FAAP
Professor of Pediatrics
Dean and Executive Vice-President
Medical College of Wisconsin
Milwaukee, Wisconsin
Otitis Media

Seema Khan, MD
Associate Professor of Pediatrics
George Washington University School of Medicine and Health Sciences
Division of Gastroenterology and Nutrition
Children's National Medical Center
Washington, DC
Embryology, Anatomy, and Function of the Esophagus
Congenital Anomalies: Esophageal Atresia and Tracheoesophageal Fistula
Obstructing and Motility Disorders of the Esophagus
Dysmotility
Hiatal Hernia
Gastroesophageal Reflux Disease
Eosinophilic Esophagitis and Non–Gastroesophageal Reflux Disease Esophagitis
Esophageal Perforation
Esophageal Varices
Ingestions

Jennifer S. Kim, MD
Assistant Professor of Pediatrics
Jaffe Food Allergy Institute
Icahn School of Medicine at Mount Sinai
New York, New York
Diagnosis of Allergic Disease
Principles of Treatment of Allergic Disease

Charles H. King, MD
Professor of International Health
Center for Global Health and Diseases
Case Western Reserve University School of Medicine
Cleveland, Ohio
Schistosomiasis (Schistosoma)
Flukes (Liver, Lung, and Intestinal)

Stephen L. Kinsman, MD
Associate Professor of Pediatrics
Division of Pediatric Neurology
Medical University of South Carolina
Charleston, South Carolina
Congenital Anomalies of the Central Nervous System

Adam Kirton, MD, MSc, FRCPC
Associate Professor of Pediatrics and Clinical Neurosciences
University of Calgary Faculty of Medicine
Director, Calgary Pediatric Stroke Program
Alberta Children's Hospital Research Institute
Calgary, Alberta, Canada
Pediatric Stroke

Priya S. Kishnani, MD, MBBS
C.L. and Sue Chen Professor of Pediatrics
Chief, Division of Medical Genetics
Duke University Medical Center
Durham, North Carolina
Defects in Metabolism of Carbohydrates

Robert L. Kitts, MD
Assistant Professor of Psychiatry
Harvard Medical School
Director, Child and Adolescent Psychiatry Fellowship
Boston Children's Hospital
Boston, Massachusetts
Rumination and Pica

Martin B. Kleiman, MD
Ryan White Professor of Pediatrics
Indiana University School of Medicine
Riley Children's Hospital
Indianapolis, Indiana
Coccidioidomycosis (Coccidioides *species*)

Bruce L. Klein, MD
Visiting Associate Professor of Pediatrics
Johns Hopkins University School of Medicine
Associate Director, Pediatric Emergency Medicine
Director, Pediatric Transport
Johns Hopkins Children's Center
Baltimore, Maryland
Interfacility Transport of the Seriously Ill or Injured Pediatric Patient
Acute Care of the Victim of Multiple Trauma

Bruce S. Klein, MD
Professor of Pediatrics and Medical Microbiology
University of Wisconsin School of Medicine
Madison, Wisconsin
Blastomycosis (Blastomyces dermatitidis)

Michael D. Klein, MD, FACS, FAAP
Arvin I. Philippart MD Endowed Chair of Pediatric Surgical Research
Professor of Surgery
Wayne State University School of Medicine
Children's Hospital of Michigan
Detroit, Michigan
Surgical Conditions of the Anus and Rectum

Robert M. Kliegman, MD
Professor and Chairman Emeritus
Department of Pediatrics
Medical College of Wisconsin
Children's Hospital of Wisconsin
Milwaukee, Wisconsin
Refeeding Syndrome
Liver Abscess
Generalized Arterial Calcification of Infancy/Idiopathic Infantile Arterial Calcification
Arterial Calcifications Caused by Deficiency of CD73
Female Genital Mutilation/Cutting
Reflex Seizures (Stimulus Precipitated Seizures)
Nodding Syndrome

William C. Koch, MD, FAAP, FIDSA
Associate Professor of Pediatrics
Medical College of Virginia / Virginia Commonwealth University
Richmond, Virginia
Parvoviruses

Patrick M. Kochanek, MD, MCCM
Ake N. Grenvik Professor of Critical Care Medicine
Vice-Chairman, Department of Critical Care Medicine
Professor of Anesthesiology, Pediatrics, Bioengineering, and Clinical and Translational Science
Director, Safar Center for Resuscitation Research
University of Pittsburgh School of Medicine
Pittsburgh, Pennsylvania
Neurologic Emergencies and Stabilization

Eric Kodish, MD
Professor and Chairman
Department of Bioethics
The Cleveland Clinic Foundation
Cleveland, Ohio
Ethics in Pediatric Care

Stephan A. Kohlhoff, MD
Assistant Professor of Pediatrics and Medicine
Associate Director, Pediatric Infectious Diseases
SUNY Downstate Medical Center
Brooklyn, New York
Chlamydia (Chlamydophila) pneumoniae
Psittacosis (Chlamydia psittaci)

Mark A. Kostic, MD
Associate Professor of Pediatrics and Emergency Medicine
Division of Pediatric Emergency Medicine
Medical College of Wisconsin
Associate Medical Director
Wisconsin Poison Center
Milwaukee, Wisconsin
Poisoning

Linda E. Krach, MD
Adjunct Professor
Department of Physical Medicine and Rehabilitation
University of Minnesota School of Medicine
President, Courage Kenny Rehabilitation Institute (part of Allina Health)
Minneapolis, Minnesota
Severe Traumatic Brain Injury

Elliot J. Krane, MD, FAAP
Professor of Pediatrics, and Anesthesiology, Perioperative, and Pain Medicine
Stanford University School of Medicine
Chief, Pediatric Pain Management
Stanford Children's Health
Lucile Packard Children's Hospital at Stanford
Stanford, California
Pediatric Pain Management

Peter J. Krause, MD
Senior Research Scientist
Department of Epidemiology and Microbial Diseases
Yale School of Public Health
Department of Medicine and Department of Pediatrics
Yale School of Medicine
New Haven, Connecticut
Babesiosis (Babesia)

Richard E. Kreipe, MD, FACCP, FSAHM, FAED
Dr. Elizabeth R. McArnarney Professor in Pediatrics funded by Roger and Carolyn Friedlander
Division of Adolescent Medicine
University of Rochester School of Medicine
Golisano Children's Hospital
Medical Director, Western New York Comprehensive Care Center for Eating Disorders
Rochester, New York
Eating Disorders

Director, Clinical and Translational Research
Stanley Manne Children's Research Institute
Ann & Robert H. Lurie Children's Hospital of Chicago
Chicago, Illinois
Pulmonary Tumors
Extrapulmonary Diseases with Pulmonary Manifestations

Margaret M. McGovern, MD, PhD
Professor and Chair
Department of Pediatrics
Stony Brook University School of Medicine
Physician-in-Chief, Stony Brook Long Island Children's Hospital
Stony Brook, New York
Lipidoses (Lysosomal Storage Disorders)
Mucolipidoses
Disorders of Glycoprotein Degradation and Structure

Heather S. McLean, MD
Associate Professor of Pediatrics
Duke University School of Medicine
Medical Director
Pediatric Hospital Medicine
Duke Children's Hospital
Durham, North Carolina
Failure to Thrive

Rima McLeod, MD
Jules and Doris Stein Research to Prevent Blindness Professor of Ophthalmology
Departments of Ophthalmology and Visual Sciences and Pediatrics
Medical Director, Toxoplasmosis Center
University of Chicago School of Medicine
Chicago, Illinois
Toxoplasmosis (Toxoplasma gondii)

Mary A. McMahon, MD
Assistant Professor
Department of Pediatrics
University of Cincinnati College of Medicine
Director, Division of Physical Medicine and Rehabilitation
Director, Physical Medicine and Rehabilitation Residency Program
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio
Spinal Cord Injury and Spinal Cord Autonomic Crisis Management

Asuncion Mejias, MD, PhD, MSCS
Assistant Professor of Pediatrics
Section of Infectious Diseases and Immunology
The Ohio State University College of Medicine
The Research Institute at Nationwide Children's Hospital
Columbus, Ohio
Hansen Disease (Mycobacterium leprae)
Mycoplasma pneumoniae
Genital Mycoplasmas (Mycoplasma hominis, Mycoplasma genitalium, *and* Ureaplasma urealyticum)

Peter C. Melby, MD
Professor of Internal Medicine (Infectious Diseases), Microbiology and Immunology, and Pathology
Director, Center for Tropical Diseases
University of Texas Medical Branch at Galveston
Galveston, Texas
Leishmaniasis (Leishmania)

Alexandra N. Menchise, MD
Pediatric Gastroenterology Fellow
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio
Metabolic Diseases of the Liver

Diane F. Merritt, MD
Professor
Department of Obstetrics and Gynecology
Director, Pediatric and Adolescent Gynecology
Washington University School of Medicine in St. Louis
St. Louis, Missouri
History and Physical Examination (Gynecology)
Vulvovaginitis
Bleeding
Breast Concerns
Neoplasms and Adolescent Screening for Human Papillomavirus

Ethan A. Mezoff, MD
Pediatric Gastroenterology Fellow
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio
Clostridium difficile *Infection*

Marian G. Michaels, MD, MPH
Professor of Pediatrics and Surgery
University of Pittsburgh School of Medicine
Division of Pediatric Infectious Diseases
Children's Hospital of Pittsburgh of UPMC
Pittsburgh, Pennsylvania
Infections in Immunocompromised Persons

Mohamad A. Mikati, MD
Wilburt C. Davison Professor of Pediatrics and Professor of Neurobiology
Chief, Division of Pediatric Neurology
Duke University Medical Center
Durham, North Carolina
Seizures in Childhood
Conditions That Mimic Seizures

Henry Milgrom, MD
Professor of Pediatrics
National Jewish Health
University of Colorado School of Medicine
Denver, Colorado
Allergic Rhinitis

E. Kathryn Miller, MD, MPH
Assistant Professor
Departments of Pediatrics and Allergy and Immunology
Vanderbilt University School of Medicine
Nashville, Tennessee
The Common Cold
Rhinoviruses

Jonathan W. Mink, MD, PhD
Frederick A. Horner MD Endowed Professor in Pediatric Neurology
Professor of Neurology, Neurobiology and Anatomy, Brain and Cognitive Sciences, and Pediatrics
Chief, Division of Child Neurology
Vice-Chair, Department of Neurology
University of Rochester Medical Center
Rochester, New York
Movement Disorders

R. Justin Mistovich, MD
Clinical Fellow
Division of Pediatric Orthopaedic Surgery
University of Pennsylvania Perelman School of Medicine
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania
The Spine

Grant A. Mitchell, MD
Professor of Pediatrics
Division of Medical Genetics
University of Montreal Faculty of Medicine
Service de Genetique Medicale
Hospital Ste-Justine
Montreal, Quebec, Canada
Tyrosine

Esi Morgan-DeWitt, MD, MSCE
Associate Professor of Pediatrics
University of Cincinnati College of Medicine
Division of Rheumatology
James M. Anderson Center for Health Systems Excellence
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio
Treatment of Rheumatic Diseases
Sarcoidosis

Anna-Barbara Moscicki, MD
Professor of Pediatrics
University of California, San Francisco
Senior Director, Pediatric Glaser Clinic
San Francisco, California
Human Papillomaviruses

Lovern R. Moseley, PhD
Department of Psychiatry
Boston Medical Center
Boston, Massachusetts
Mood Disorders
Disruptive, Impulse-Control, and Conduct Disorders

Beth Moughan, MD
Professor of Clinical Pediatrics
Assistant Dean, Affiliate Faculty Development
Associate Chair, Clinical Affairs
Section Chief, Ambulatory Pediatrics
Temple University School of Medicine
Philadelphia, Pennsylvania
Sporotrichosis (Sporothrix schenckii)

James R. Murphy, PhD
Professor of Pediatrics
Director, Pediatric Infectious Disease Research
University of Texas Health Science Center
Houston, Texas
Campylobacter
Yersinia

Kevin P. Murphy, MD
Medical Director Pediatric Rehabilitation
Sanford Health Systems
Bismarck, North Dakota;
Medical Director, Gillette Children's Specialty Healthcare
Duluth Clinic
Duluth, Minnesota
Management of Musculoskeletal Injury
Specific Sports and Associated Injuries

Timothy F. Murphy, MD
Distinguished Professor
Director, UB Clinical and Translational Research Center
University at Buffalo, State University of New York
School of Medicine and Biomedical Sciences
Buffalo, New York
Moraxella catarrhalis

Thomas S. Murray, MD, PhD
Associate Professor of Medical Sciences
Quinnipiac University Frank H Netter MD School of Medicine
Hamden, Connecticut
Listeria monocytogenes
Pseudomonas, Burkholderia, *and* Stenotrophomonas

René P. Myers, MD
Chief Resident
Department of Plastic Surgery
University of Rochester Medical Center
Rochester, New York
Deformational Plagiocephaly

Mindo J. Natale, PsyD
Assistant Professor of Psychology
University of South Carolina School of Medicine
Senior Staff Psychologist
GHS Children's Hospital
Greenville, South Carolina
Neurodevelopmental Function and Dysfunction in the School-Age Child

William A. Neal, MD
Professor of Pediatrics
Division of Pediatric Cardiology
West Virginia University School of Medicine
Morgantown, West Virginia
Disorders of Lipoprotein Metabolism and Transport

Maureen R. Nelson, MD
Pediatric Subspecialty Services
Dell's Children's Medical Center of Central Texas
Austin, Texas
Birth Brachial Plexus Palsy

Jayne M. Ness, MD, PhD
Associate Professor of Pediatrics
Division of Pediatric Neurology
University of Alabama, Birmingham
Birmingham, Alabama
Demyelinating Disorders of the Central Nervous System

Kathleen A. Neville, MD, MS
Associate Professor of Pediatrics
University of Missouri—Kansas City School of Medicine
Director, Experimental Therapeutics in Pediatric Cancer
Department of Pediatric Hematology/Oncology
Children's Mercy Hospitals and Clinics
Kansas City, Missouri
Pediatric Pharmacogenetics, Pharmacogenomics, and Pharmacoproteomics

Mary A. Nevin, MD
Associate Professor of Pediatrics
Northwestern University Feinberg School of Medicine
Department of Pulmonary and Critical Care Medicine
Ann & Robert H. Lurie Children's Hospital of Chicago
Chicago, Illinois
Pulmonary Hemosiderosis
Pulmonary Embolism, Infarction, and Hemorrhage

Jane W. Newburger, MD
Commonwealth Professor of Pediatrics
Harvard Medical School
Associate Cardiologist-in-Chief, Research and Education
Director, Cardiac Neurodevelopmental Program
Director, Kawasaki Program
Children's Hospital Boston
Boston, Massachusetts
Kawasaki Disease

Peter E. Newburger, MD
Ali and John Pierce Professor of Pediatric Hematology/Oncology
Vice-Chair for Research
Department of Pediatrics
University of Massachusetts Medical School
Worcester, Massachusetts
Leukopenia
Leukocytosis

Linda S. Nield, MD
Professor of Pediatrics
Director, Pediatrics Residency Program
West Virginia University School of Medicine
Morgantown, West Virginia
Fever
Fever Without a Focus

Susan Niermeyer, MD, MPH, FAAP
Professor of Pediatrics
Section of Neonatology
University of Colorado School of Medicine
Aurora, Colorado
Altitude-Associated Illness in Children (Acute Mountain Sickness)

Zehava L. Noah, MD
Associate Professor of Pediatrics
Northwestern University Feinberg School of Medicine
Division of Pediatric Critical Care Medicine
Ann & Robert H. Lurie Children's Hospital of Chicago
Chicago, Illinois
Chronic Severe Respiratory Insufficiency

Lawrence M. Nogee, MD
Professor of Pediatrics
Department of Pediatrics
Division of Neonatology and Perinatology
Johns Hopkins University School of Medicine
Baltimore, Maryland
Diffuse Lung Diseases in Childhood

Robert L. Norris, MD, FACEP, FAAEM
Professor of Surgery
Chief, Division of Emergency Medicine
Stanford University Medical Center
Stanford, California
Envenomations

Anna Nowak-Węgrzyn, MD
Associate Professor of Pediatrics
Jaffe Food Allergy Institute
Icahn School of Medicine at Mount Sinai
New York, New York
Serum Sickness
Food Allergy and Adverse Reactions to Foods

Stephen K. Obaro, MD, PhD, FRCPCH
Professor of Pediatrics
Division of Infectious Diseases
University of Nebraska Medical Center
Omaha, Nebraska
Nonvenereal Treponemal Infections
Relapsing Fever (Borrelia)

Makram M. Obeid, MD
Clinical Fellow in Neurology
Boston Children's Hospital
Boston, Massachusetts
Conditions That Mimic Seizures

Hope L. O'Brien, MD
Assistant Professor of Pediatrics and Neurology
University of Cincinnati College of Medicine
Director, Young Adult Headache Program
Division of Neurology
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio
Headaches

Theresa J. Ochoa, MD
Associate Professor of Epidemiology and Pediatrics
The University of Texas Health Science Center at Houston
Houston, Texas;
Universidad Peruana Cayetano Heredia
Lima, Peru
Shigella
Escherichia coli

Robin K. Ohls, MD
Professor of Pediatrics
University of New Mexico School of Medicine
Albuquerque, New Mexico
Development of the Hematopoietic System

Jean-Marie Okwo-Bele, MD, MPH
Director
Immunization, Vaccines, and Biologicals Department
World Health Organization
Geneva, Switzerland
International Immunization Practices

Keith T. Oldham, MD
Professor and Chief
Division of Pediatric Surgery
Medical College of Wisconsin
Children's Hospital of Wisconsin
Milwaukee, Wisconsin
Acute Appendicitis
Inguinal Hernias
Epigastric Hernia

Joyce L. Oleszek, MD
Associate Professor
Department of Physical Medicine and Rehabilitation
University of Colorado School of Medicine
Attending Physician
Children's Hospital Colorado
Denver, Colorado
Spasticity

Scott E. Olitsky, MD
Professor of Ophthalmology
University of Kansas School of Medicine
University of Missouri—Kansas City School of Medicine
Section Chief, Ophthalmology
Children's Mercy Hospitals and Clinics
Kansas City, Missouri
Growth and Development (Eye)
Examination of the Eye
Abnormalities of Refraction and Accommodation
Disorders of Vision
Abnormalities of Pupil and Iris

Abnormalities of the Cornea
Abnormalities of the Lens
Disorders of the Uveal Tract
Disorders of the Retina and Vitreous
Abnormalities of the Optic Nerve
Childhood Glaucoma
Orbital Abnormalities
Orbital Infections
Injuries to the Eye

John M. Olsson, MD, CPE
Professor of Pediatrics
Division Chief, General Pediatrics
Brody School of Medicine
East Carolina University
Greenville, North Carolina
The Newborn

Amanda K. Ombrello, MD
Staff Clinician
National Human Genome Research Institute
National Institutes of Health
Bethesda, Maryland
Hereditary Periodic Fever Syndromes and Other Systemic Autoinflammatory Diseases
Amyloidosis

Susan R. Orenstein, MD
Professor Emerita
University of Pittsburgh School of Medicine
Division of Pediatric Gastroenterology
Children's Hospital of Pittsburgh of UPMC
Pittsburgh, Pennsylvania
Embryology, Anatomy, and Function of the Esophagus
Congenital Anomalies: Esophageal Atresia and Tracheoesophageal Fistula
Obstructing and Motility Disorders of the Esophagus
Dysmotility
Hiatal Hernia
Gastroesophageal Reflux Disease
Eosinophilic Esophagitis and Non–Gastroesophageal Reflux Disease Esophagitis
Esophageal Perforation
Esophageal Varices
Ingestions

Walter A. Orenstein, MD, DSc (Hon)
Professor of Medicine and Pediatrics
Associate Director, Emory Vaccine Center
Emory University
Atlanta, Georgia
Immunization Practices

Marisa Osorio, DO
Acting Assistant Professor
Department of Rehabilitation Medicine
University of Washington School of Medicine
Seattle Children's Hospital
Seattle, Washington
Ambulation Assistance

Patrick O'Toole, MD
Clinical Fellow
Division of Pediatric Orthopaedic Surgery
University of Pennsylvania Perelman School of Medicine
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania
The Neck

Judith A. Owens, MD, MPH
Associate Professor
Harvard Medical School
Director of Sleep Medicine
Boston Children's Hospital
Boston, Massachusetts
Sleep Medicine

Seza Özen, MD
Professor of Paediatrics
Division of Paediatric Rheumatology
Hacettepe University
Ankara, Turkey
Behçet Disease

Charles H. Packman, MD
Professor of Medicine
University of North Carolina School of Medicine
Levine Cancer Institute, Hematologic Oncology and Blood Disorders
Charlotte, North Carolina
Hemolytic Anemias Resulting from Extracellular Factors—Immune Hemolytic Anemias

Priya Pais, MBBS, MS
Assistant Professor of Pediatrics
Division of Nephrology
Medical College of Wisconsin
Wauwatosa, Wisconsin
Lower Urinary Tract Causes of Hematuria
Introduction to the Child with Proteinuria
Fixed Proteinuria
Nephrotic Syndrome
Cortical Necrosis

Tonya M. Palermo, PhD
Professor
Department of Anesthesiology
University of Washington School of Medicine
Seattle Children's Hospital Research Institute
Seattle, Washington
Pediatric Pain Management

Cynthia G. Pan, MD
Professor of Pediatrics
Section Head, Pediatric Nephrology
Medical College of Wisconsin
Medical Director, Pediatric Dialysis and Transplant Services
Children's Hospital of Wisconsin
Milwaukee, Wisconsin
Introduction to Glomerular Diseases
Clinical Evaluation of the Child with Hematuria
Isolated Glomerular Diseases with Recurrent Gross Hematuria
Glomerulonephritis Associated with Infections
Glomerulonephritis Associated with Systemic Lupus Erythematosus

Diane E. Pappas, MD, JD
Professor
Department of Pediatrics
University of Virginia School of Medicine
Charlottesville, Virginia
Sinusitis
Retropharyngeal Abscess, Lateral Pharyngeal (Parapharyngeal) Abscess, and Peritonsillar Cellulitis/Abscess

Elizabeth P. Parks, MD, MSCE
Assistant Professor of Pediatrics
Division of Gastroenterology, Hepatology, and Nutrition
University of Pennsylvania Perelman School of Medicine
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania
Nutritional Requirements
Feeding Healthy Infants, Children, and Adolescents

John S. Parks, MD, PhD
Professor of Pediatrics
Division of Pediatric Endocrinology
Emory University School of Medicine
Atlanta, Georgia
Hormones of the Hypothalamus and Pituitary
Hypopituitarism

Maria Jevitz Patterson, MD, PhD
Professor Emeritus of Microbiology and Molecular Genetics
Michigan State University College of Human Medicine
East Lansing, Michigan
Syphilis (Treponema pallidum)

Timothy R. Peters, MD
Associate Professor of Pediatrics
Section of Pediatric Infectious Diseases
Wake Forest University School of Medicine
Winston-Salem, North Carolina
Streptococcus pneumoniae (*Pneumococcus*)

Larry K. Pickering, MD
Senior Advisor to the Director
National Center for Immunization and Respiratory Diseases
Executive Secretary
Advisory Committee for Immunization Practices
Centers for Disease Control and Prevention
Adjunct Professor of Pediatrics
Emory University School of Medicine
Atlanta, Georgia
Immunization Practices

Misha L. Pless, MD
Associate Professor of Neurology
Harvard Medical School
Chief, Division of Neuro-ophthalmology
Chief, Division of General Neurology
Director, Neurology Urgent Access Center
Massachusetts General Hospital
Boston, Massachusetts
Idiopathic Intracranial Hypertension/Pseudotumor Cerebri

Laura S. Plummer, MD
Assistant Professor
Department of Ophthalmology
University of Missouri—Kansas City School of Medicine
Children's Mercy Hospital
Kansas City, Missouri
Growth and Development (Eye)
Examination of the Eye

Preface

Whoever saves one life it is considered as if they saved an entire world.
— Babylonian Talmud

The 20th edition of *Nelson Textbook of Pediatrics* continues in its tradition of being an essential resource for pediatricians as they diagnose and treat the infants, children, and adolescents of the 21st century. The 20th edition has been thoroughly revised, updated, and edited to keep up with the growing data accumulated from basic, clinical, and population-based research. The promise that translational medicine will improve the lives of all children is greater than ever. Knowledge of human development, behavior, and diseases from the molecular to sociologic levels is increasing at fantastic rates, leading to greater understanding of health and illness in children and substantial improvements in health quality for those who have access to health care. These exciting scientific advances also provide hope to effectively address prevention and treatment of new and emerging diseases threatening children and their families.

The field of pediatrics encompasses advocacy for all children throughout the world and must address societal inequalities of important resources required for normal development, as well as protection from natural and manmade disasters. Unfortunately, many children throughout the world have not benefited from the significant advances in the prevention and treatment of health-related problems, primarily because of a lack of political will and misplaced priorities. For our increasing knowledge to benefit all children and youth, medical advances and good clinical practice must always be coupled with effective advocacy.

This new edition of *Nelson Textbook of Pediatrics* attempts to provide the essential information that practitioners, house staff, medical students, and other care providers involved in pediatric health care throughout the world need to understand to effectively address the enormous range of biologic, psychologic, and social problems that our children and youth may face. Our goal is to be comprehensive yet concise and reader friendly, embracing both the new advances in clinical science and the time-honored art of pediatric practice.

The 20th edition is reorganized and revised from the previous edition. There are many additions of new diseases and new chapters, as well as substantial expansion or significant modification of others. In addition many more tables, photographs, imaging studies, and illustrative figures, as well as up-to-date references, have been added. Although, to an ill child and his or her family and physician, even the rarest disorder is of central importance, all health problems cannot possibly be covered with the same degree of detail in one general textbook of pediatrics. Thus, leading articles and subspecialty texts are referenced and should be consulted when more information is desired.

The outstanding value of the 20th edition of the textbook is due to its expert and authoritative contributors. We are all indebted to these dedicated authors for their hard work, knowledge, thoughtfulness, and good judgment. Our sincere appreciation also goes to Kate Dimock and Jennifer Shreiner at Elsevier and to Carolyn Redman at the Pediatric Department of the Medical College of Wisconsin. In addition, we thank Barbara Ruggeri for her excellent library science skills and for keeping us up to date with the literature. We have all worked hard to produce an edition that will be helpful to those who provide care for children and youth and to those desiring to know more about children's health worldwide.

In this edition we have had informal assistance from many faculty and house staff of the departments of pediatrics at the Medical College of Wisconsin, Wayne State University School of Medicine, University of Pennsylvania School of Medicine, and University of Rochester School of Medicine. The help of these individuals and of the many practicing pediatricians from around the world who have taken the time to offer thoughtful feedback and suggestions is always greatly appreciated and helpful.

Last and certainly not least, we especially wish to thank our families for their patience and understanding, without which this textbook would not have been possible.

Nelson TEXTBOOK *of* PEDIATRICS

The Field of Pediatrics

PART I

Chapter 1

Overview of Pediatrics

Bonita F. Stanton and Richard E. Behrman

Pediatrics is the only discipline dedicated to all aspects of the well-being of infants, children, and adolescents, including their health; their physical, mental, and psychologic growth and development; and their opportunity to achieve full potential as adults. Pediatricians must be concerned not only with particular organ systems and biologic processes, but also with environmental, social, and political influences, which have a major impact on the health and well-being of children and their families.

Children cannot advocate for themselves. As the professionals whose entire purpose is to advance the well-being of children, pediatricians must be advocates for the individual child and for all children, irrespective of culture, religion, gender, race, or ethnicity or of local, state, or national boundaries. The more politically, economically, or socially disenfranchised a population or a nation is, the greater the need for advocacy for children. The young are often among the most vulnerable or disadvantaged in society and thus their needs require special attention. As divides between nations blur through modern transportation, communication and economics, through global climate change, through contemporary means of warfare, and through uneven development within and across countries, a global, rather than a national, perspective for the field of pediatrics becomes both a reality and a necessity. The interrelation of health issues across the globe has achieved widespread recognition in the wake of the SARS (severe acute respiratory syndrome) and AIDS epidemics, expansions in the pandemics of cholera and West Nile virus, war and bioterrorism, the tsunami of 2004, the global recession beginning in 2008, the "Arab Spring" beginning in 2010, and the growing severity of hurricanes and cyclones.

More than a century ago, pediatrics emerged as a medical specialty in response to increasing awareness that the health problems of children differ from those of adults and that a child's response to illness and stress varies with age. In 1959, the United Nations issued the Declaration of the Rights of the Child, articulating the universal presumption that children everywhere have fundamental needs and rights.

VITAL STATISTICS ABOUT CHILD HEALTH (See Also Chapter 1.1)

From 1990 to 2010, the world population grew at an annual rate of 1.3% per yr, down from 1.8% annually during the prior 20 yr. The annual growth rate from 2010 to 2030 is expected to further decline to 0.9%. Worldwide, children younger than age 18 yr account for 2.2 billion (30%) of the world's 7.02 billion persons. In 2010, there were an estimated 135 million births worldwide, 121 million (90%) of which were in developing countries. India, with 27.2 million births annually, is home to the largest number, followed by China at 16.5 million.

Despite global interconnectedness, the health problems of children and youth vary widely between and within populations in the nations of the world depending on a number of often interrelated factors. These factors include (1) economic considerations (economic disparities); (2) educational, social, and cultural considerations; (3) the prevalence and ecology of infectious agents and their hosts; (4) climate and geography; (5) agricultural resources and practices (nutritional resources); (6) stage of industrialization and urbanization; (7) the gene frequencies for some disorders; (8) the health and social welfare infrastructure available within these countries; and (9) political focus and stability. The state of health of any community is defined by the incidence of illness and by data from studies that show the changes that occur with time and in response to programs of prevention, case finding, therapy, and surveillance. To ensure that the needs of children and adults across the globe were not obscured by local needs, in 2000 the international community established 8 Millennium Development Goals (MDGs) to be achieved by 2015 (http://www.countdown2015mnch.org). Although all 8 MDGs impact child well-being, MDG 4 ("Reduce by two-thirds, between 1990 and 2015, the under-five mortality rate") is exclusively focused on children.

Great strides have been made toward achieving the MDGs. Globally, there has been a reduction in under-5 mortality since 1990 from 90 to 48 deaths per 1,000 live births, with a reduction from 15 to 6 deaths in developed countries and from 99 to 53 deaths in developing countries. With the exception of sub-Saharan Africa and Oceania, all global regions reduced their under-5 mortality rate by more than half from 1990 to 2012. There were nearly 13 million under-5 deaths in 1990; 2006 marked the first year that there were fewer than 10 million deaths (9.7 million), which further decreased to 9.0 million in 2007, 8.8 million in 2008, 7.6 million in 2010, and 6.6 million in 2012. Despite these substantial successes, the annual rate of reduction in the global under-5 mortality rate of 3.9% remains below the MDG targeted rate of 4.4%, necessary to achieve the goal of a ⅔ reduction in the 1990 rate by 2015 (Fig. 1-1).

The infant mortality rate (deaths of children <1 yr) accounts for 83% of the under-5 mortality rate in industrialized countries, but only 64% of the rate in the least-developed nations. Neonatal (<1 mo) death contributes substantially to the under-5 mortality rate, growing in proportion as the under-5 death rate decreases. The neonatal mortality rate has been slower to decline. Globally, the neonatal mortality rate of 23 per 1,000 live births represents 57% of the infant mortality rate of 40 per 1,000 live births and 40% of the under-5 death rate (up from 37% in 1990). The neonatal mortality rate is responsible for 50% of the under-5 mortality rate in industrialized nations, 40% of the rate in developing countries, but only 33% in the least-developed countries. Most of the decline in infant mortality in the United States and other industrialized countries since 1970 is attributable to a decrease in the birthweight-specific infant mortality rate related to neonatal intensive care, not to the prevention of low-birthweight births (see Chapter 93).

Across the globe, there are significant variations in infant mortality rates by nation, by region, by economic status, and by level of industrial development, the categorizations employed by the World Bank and the United Nations (Table 1-1; see also Figs. 1-8 and 1-9). As of 2012 three nations in the world still have an under-5 mortality rate of ≥150 per 1,000 live births (Sierra Leone, 182; Angola, 164, Chad, 150), with an additional 13 nations having ≥100 deaths per 1,000 live births. Although these 3 nations are among the poorest in the world, many of their economic matches have enjoyed greater improvements in child survival in recent years, demonstrating that economics are important but that other factors, such as political will, are also important. Similarly, in 2012, the United States, with one of the 10 highest gross national incomes in the world, had an under-5 mortality rate of 7 per 1,000 live births; 39 nations had lower under-5 mortality rates, with 9 countries having a rate of 3 and 2 countries having a rate of 2 per 1,000 live births.

Causes of under-5 mortality differ markedly between developed and developing nations. In developing countries, 66% of all deaths resulted from infectious and parasitic diseases. Among the 42 countries having

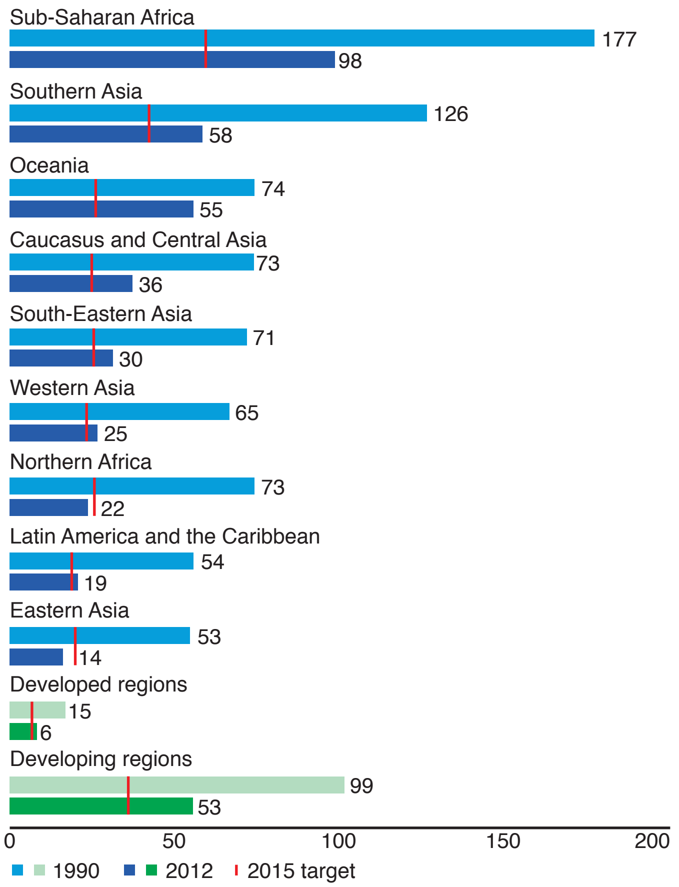

Figure 1-1 Despite substantial progress, the world is still falling short of the MDG child mortality target. Under-5 mortality rate per 1,000 live births, 1990 and 2012 (deaths per 1,000 live births). *(From* Millennium Development Goals Report, 2014. *New York, 2014, United Nations, p. 24.)*

90% of childhood deaths, diarrheal disease accounted for 22% of deaths, pneumonia 21%, malaria 9%, AIDS 3%, and measles 1%. Neonatal causes contributed to 33%. The contribution for AIDS varies greatly by country, being responsible for a substantial proportion of deaths in some countries and negligible amounts in others. Likewise, there is substantial co-occurrence of infections; a child may die with HIV, malaria, measles, and pneumonia. Infectious diseases are still responsible for much of the mortality in developing countries. In the United States, pneumonia (and influenza) accounted for only 2% of under-5 deaths, with only negligible contributions from diarrhea and malaria. Unintentional injury is the most common cause of death among U.S. children ages 1-4 yr, accounting for approximately 33% of deaths, followed by congenital anomalies (11%), homicides (9%), and malignant neoplasms (8%). Other causes accounted for <5% of total mortality within this age group (Table 1-2). Although unintentional injuries in developing countries are proportionately less important causes of mortality than in developed countries, their absolute rates and their contributions to morbidity are substantially greater.

Just as economic status of a country as a whole is closely correlated with child survival, so too is relative wealth within a country. Poorer children in nations worldwide have higher death rates than their wealthier national counterparts (Fig. 1-2).

Causes of death vary by developmental status of the nation. In the United States, the 3 leading causes of death among infants were congenital anomalies, disorders related to gestation and low birthweight, and sudden infant death (see Table 1-2). By contrast, in developing countries, the majority of infant deaths are caused by infectious diseases; even in the neonatal period, 24% of deaths are caused by severe infections and 7% by tetanus. Although immunization rates remain higher in industrialized nations compared to developing nations, this gap is closing. In 2010, immunization percentage rates against diphtheria, pertussis, tetanus, measles, and polio were in the mid-90s; comparable levels in developing countries were in the mid-80s, with rates in the least-developed countries very close. In developing countries, 29% of neonatal deaths are caused by birth asphyxia and 24% are caused by complications of prematurity.

A consistently robust predictor of infant mortality across the globe is a poor level of maternal education (consequently, another of the MDGs addresses the need for universal access to schooling for girls; Fig. 1-3). Other maternal risk characteristics, such as unmarried status, adolescence, and high parity, correlate with increased risk of postneonatal mortality and morbidity and low birthweight.

Table 1-1 Child Health Indicators Worldwide by Region

	Mortality Rate by Yr Per 1,000 Live Births					GROSS NATIONAL PER CAPITA INCOME	LIFE EXPECTANCY AT BIRTH	PRIMARY SCHOOL ATTENDANCE
	UNDER-5		INFANT MORTALITY		NEONATAL MORTALITY			
	1990	2012	1990	2012	2012	2012	2012	2008-2011
Sub-Saharan Africa	177	98	107	64	32	$1,397	56 yr	77%
Eastern and Southern Africa	163	77	101	51	28	$1,729	59 yr	87%

Table 1-2 Leading Causes of Death and Numbers of Deaths, According to Age: United States, 2010

AGE AND RANK ORDER	CAUSE OF DEATH	NUMBER	PERCENT OF TOTAL DEATHS
Under 1 yr	All causes	24,586	100%
	Congenital malformations, deformations, and chromosomal abnormalities	5,107	21%
	Disorders related to short gestation and low birthweight, not elsewhere classified	4,148	17%
	Sudden infant death syndrome	2,063	8%
	Newborn affected by maternal complications of pregnancy	1,561	6%
	Unintentional injuries	1,110	5%
	Newborn affected by complications of placenta, cord, and membranes	1,030	4%
	Bacterial sepsis of newborn	583	2%
	Respiratory distress of newborn	514	2%
	Diseases of the circulatory system	507	2%
	Newborn affected by maternal complications of pregnancy	472	2%
1-4 yr	All causes	4,316	100%
	Unintentional injuries	1,394	32%
	Congenital malformations, deformations, and chromosomal abnormalities	507	12%
	Homicide	385	9%
	Malignant neoplasms	346	8%
	Diseases of heart	159	4%
	Influenza and pneumonia	91	1%
	Septicemia	62	1%
	In situ neoplasms, benign neoplasms, and neoplasms of uncertain or unknown behavior	59	1%
	Certain conditions originating in the perinatal period	52	1%
	Chronic lower respiratory diseases	51	1%
5-14 yr	All causes	5,279	100%
	Unintentional injuries	1,643	31%
	Malignant neoplasms	916	17%
	Congenital malformations, deformations, and chromosomal abnormalities	298	6%
	Suicide	274	5%
	Homicide	261	5%
	Diseases of heart	185	4%
	Chronic lower respiratory diseases	133	3%
	Cerebrovascular diseases	90	2%
	In situ neoplasms, benign neoplasms, and neoplasms of uncertain or unknown behavior	82	2%
	Influenza and pneumonia	71	1%
15-24 yr	All causes	29,551	100%
	Unintentional injuries	12,341	30%
	Homicide	4,678	16%
	Suicide	4,600	16%
	Malignant neoplasms	1,604	5%
	Diseases of heart	1,028	3%
	Congenital malformations, deformations, and chromosomal abnormalities	412	1%
	Cerebrovascular diseases	190	<1%
	Influenza and pneumonia	181	<1%
	Diabetes mellitus	165	<1%
	Pregnancy, childbirth, and the puerperium	163	<1%

THE CHANGING PEDIATRIC WORLD

A profound improvement in child health within industrialized nations occurred in the 20th century with the introduction of antibacterial disinfectants, antibiotic agents, and vaccines. Efforts to control infectious diseases were complemented by better understanding of nutrition. In the United States, Canada, and parts of Europe, new and continuing discoveries in these areas led to establishment of public well-child clinics for low-income families. Although the timing of control of infectious disease was uneven around the globe, this focus on control was accompanied by significant decreases in morbidity and mortality in all countries. The smallpox eradication program of the 1970s resulted in the global eradication of smallpox in 1977. The introduction in the 1970s of the Expanded Program of Immunizations (universal vaccination against polio, diphtheria, measles, tuberculosis, tetanus, and pertussis) by the World Health Organization (WHO) and United Nations Children's Fund (UNICEF) has resulted in an estimated annual reduction of 1-2 million deaths per year globally. Recognizing the importance of prevention of infectious diseases to the health of children, several countries among the 50 ranked by the World Bank as among the poorest nations (per capita income <$750/yr) have invested heavily in infectious disease control through the development of internal vaccine production capability. From 2000 to 2010, globally there was a 74% decline (with sub-Saharan Africa witnessing an 85% decline) in deaths caused by measles as a result of increased vaccination. As diarrheal diseases continued through the mid-1970s to account for ≈25% of infant and childhood deaths in developing countries (~4 million deaths per year at that time), attention turned to the development and utilization of oral resuscitation fluids to sustain children through potentially life-threatening episodes of acute diarrheal diseases. Oral rehydration solutions are largely credited with the current reduction of diarrheal deaths annually to 1.5 million. Substantial improvements have been witnessed in malaria control (global decrease of incidence by 17% and mortality rate by 25% since 2000). There have been substantial increases in the percent of households having insecticide-treated bed nets and in treatment of children with fever in endemic areas receiving antimalarial drugs.

In the later 20th century, with improved control of infectious diseases (including the elimination of polio in the Western hemisphere)

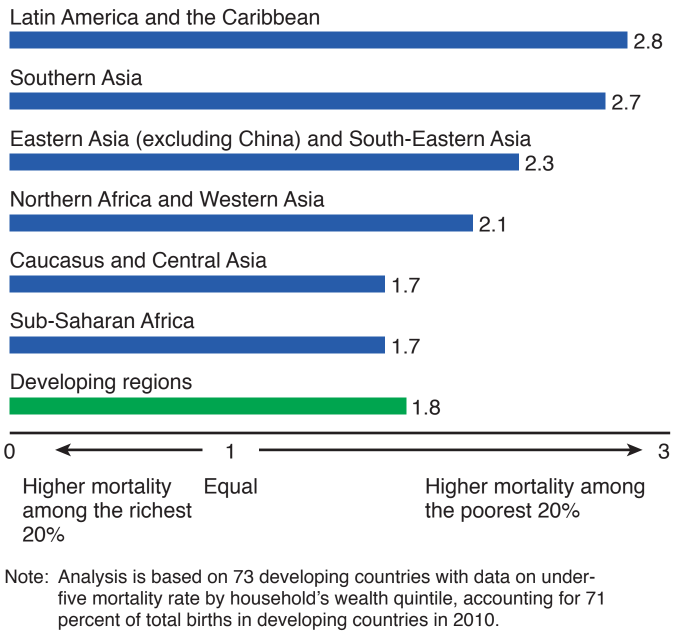

Figure 1-2 Ratio of under-5 mortality rate for children from the poorest 20% quintile of households to children from the richest 20% of households, 2000/2010. *(From* Millennium Development Goals Report, 2012. *New York, 2012, United Nations, p. 28.)*

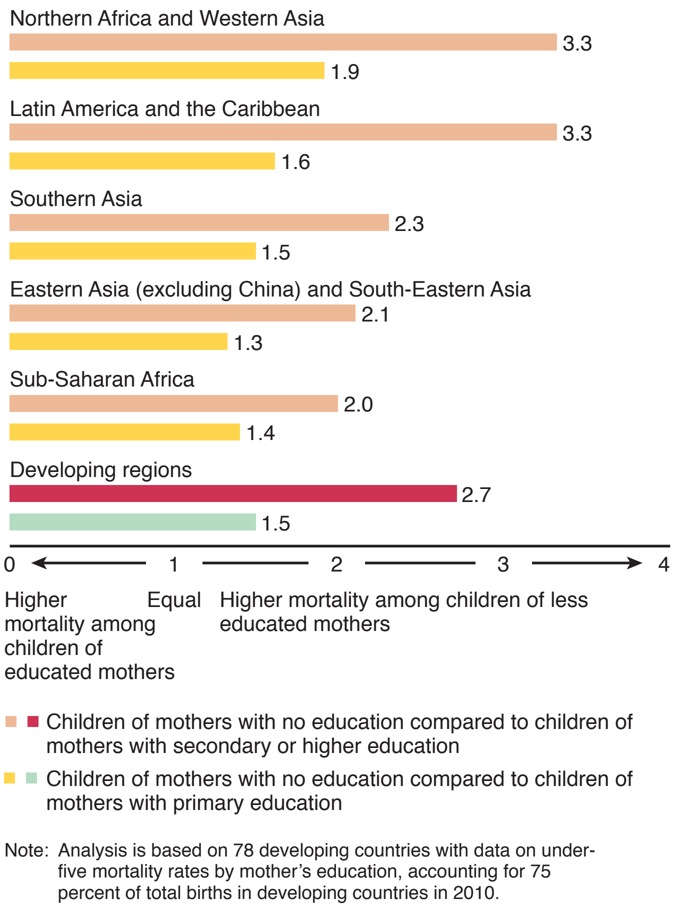

Figure 1-3 Ratio of under-5 mortality rate of children of mothers with no education compared to the rate of children of mothers with higher education. *(From* Millennium Development Goals Report, 2012. *New York, 2012, United Nations, p. 28.)*

through both prevention and treatment, pediatric medicine in industrialized nations increasingly turned its attention to a broad spectrum of conditions. These included both potentially lethal conditions and temporarily or permanently handicapping conditions; among these disorders were leukemia, cystic fibrosis, diseases of the newborn infant, congenital heart disease, mental retardation, genetic defects, rheumatic diseases, renal diseases, and metabolic and endocrine disorders.

Increasing attention has also been given to behavioral and social aspects of child health, ranging from reexamination of child-rearing practices to creation of major programs aimed at prevention and management of abuse and neglect of infants and children. Developmental psychologists, child psychiatrists, neuroscientists, sociologists, anthropologists, ethnologists, and others have brought us new insights into human potential, including new views of the importance of the environmental circumstances during pregnancy, surrounding birth, and in the early years of child rearing. The later 20th century witnessed the beginning of nearly universal acceptance by pediatric professional societies of attention to normal development, child rearing, and psychosocial disorders across the continents. In the past decade, irrespective of level of industrialization, nations have developed programs addressing not only causes of mortality and physical morbidity (such as infectious diseases and protein-calorie malnutrition), but also factors leading to decreased cognition and thwarted psychosocial development, including punitive child-rearing practices (whether at home or in school) and wife abuse, child labor, undernutrition, war, and poor-quality schooling. Obesity is recognized as a major health risk not only in industrialized nations, but increasingly in transitional countries. Progress at the turn of the 21st century in unraveling the human genome offers for the first time the realization that significant genetic screening, individualized pharmacotherapy, and genetic manipulation will be a part of routine pediatric treatment and prevention practices in the future. The prevention implications of the genome project give rise to the possibility of reducing costs for the care of illness but also increase concerns about privacy issues (see Chapter 3).

Although local famines and disasters, and regional and national wars have periodically disrupted the general trend for global improvement in child health indices, it was not until the advent of the AIDS epidemic in the later 20th century that the first substantial global erosion of progress in child health outcomes occurred. This erosion resulted in ever-widening gaps between childhood health indices in sub-Saharan Africa compared to the rest of the world. From 1990 to 2002, life expectancy in sub-Saharan Africa decreased from 50 yr to 46 yr. However, as of 2008, it had returned to 52 yr and in 2012 was 56 yr. Wide distribution of effective antiretroviral therapy (Fig. 1-4), aggressive HIV prevention education, and increased access to antitubercular drugs have been important in these successes, but continued successes will require sustained international support. Despite this positive news, children with HIV remain the least-likely group to receive antiretroviral treatment. Despite these gains, diseases once confined to limited geographic niches, including West Nile virus, and diseases previously uncommon among humans, such as the avian flu virus, increased awareness of the interconnectedness of health around the world and the impact of global warming. Formerly perceived as a problem of industrialized nations, motor vehicle crashes are now recognized as a major cause of mortality in developing countries.

MORBIDITIES AMONG CHILDREN

Adequately addressing special healthcare needs is important in all countries, both to minimize loss of life and to maximize the potential of each individual.

In the United States, ≈70% of all pediatric hospital bed days are for chronic illnesses; 80% of pediatric health expenditures are for 20% of children. Approximately 14% of U.S. children have special healthcare needs, ranging from 10% to 19.8% across the 50 states and the District of Columbia. One in 5 households with children had ≥1 children with special healthcare needs (see Chapter 42). Significantly, more poor children and minority children have special healthcare needs.

Although there are numerous chronic conditions and the prevalence of these disorders vary by population, 2 of these morbidities—asthma

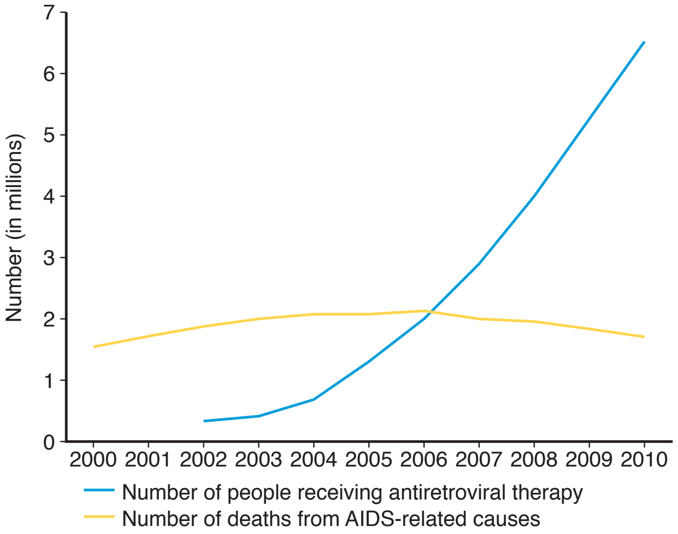

Figure 1-4 Number of persons receiving antiretroviral therapy and deaths caused by HIV over time. *(From* Millennium Development Goals Report, 2012. *New York, 2012, United Nations, p. 41.)*

and nutrition disorders—have an increasing presence worldwide and are associated with substantial health consequences and costs.

More than 80% of **asthma-related deaths** occur among children living in developing countries. The Centers for Disease Control and Prevention estimated that 10% of U.S. children have asthma, with particularly high rates among Puerto Rican and black children. Between 2001 and 2009, the prevalence of asthma increased by 50% among black children. The International Study of Asthma and Allergies in Childhood has presented evidence for a substantial global burden of childhood asthma, although rates vary substantially between and within countries. The highest annual prevalence rates are in the United Kingdom, Australia, New Zealand, and Ireland, with the lowest rates in Eastern European countries, Indonesia, China, Taiwan, India, and Ethiopia (see Chapter 144).

Chronic disorders of nutrition occur in a variety of forms. Long recognized as a major threat to child welfare, malnutrition (undernutrition) has been steadily decreasing over the past decades. Children in industrialized countries have greatly benefitted from a wide range of supplemental feeding programs (see Chapters 45 and 46); malnutrition in such nations is generally a result of selected deficiencies rather than overall undernutrition. An estimated 1% of children in the United States have some form of malnutrition. Moderate and severe malnutrition continue to impact children in developing nations. Although great progress has been made in this regard over the past several decades, children in the poorest nations and children whose families are in the lower economic quintile in a broader range of countries continue to struggle. In the period 2011–2013, 14% of children younger than age 5 yr in developing countries and 25% of those in the least-developed countries suffer from moderate/severe malnutrition; South Asia and West/Central Africa suffer from the highest rates of moderate/severe malnutrition at 42% and 23%, respectively. Rates of stunting (>2 SD below median height for age) are higher, at 29% and 41%, for children in developing and the least-developed countries, respectively (see Chapter 46).

The global epidemic of **overweight/obesity** is also significant. In the United States, 30% of children and adolescents are overweight or obese, representing a 3-fold increase over the past 30 yr. Rates of obesity for boys whose parents did not graduate from high school are 3-fold higher than those whose parents received at least a bachelor's degree; for girls, the difference is 2-fold. Similar rates have been reported from Australia and multiple countries in Europe, Egypt, Chile, Peru, and Mexico (see Chapter 47). The WHO estimates that globally 42 million children younger than the age of 5 yr are overweight; ~35 million of these live in developing countries.

Chronic cognitive morbidities represent another substantial problem. Although different diagnostic criteria have been applied, attention-deficit/hyperactivity disorder has been identified in 5-12% of children in countries across the globe, with a worldwide estimated prevalence of 5.29%. Rates exceeding 10% have been reported in the United States, New Zealand, Australia, Spain, Italy, Colombia, and Great Britain. Variations in cultural tolerance and/or differences in screening approaches or tools may account for some of the differences in prevalence of the disorder by country, but genetic and gene–environmental interactions may also play a role. Despite variations in rate, the condition is universal. Beyond the personal and familial stress caused by the disorder, costs to the educational systems are considerable. In countries where they are available, drug costs are considerable; in the United States, annual costs for drug treatments for attention-deficit/hyperactivity disorder are estimated to exceed $4 billion. In developing countries without resources for special education, these children are unlikely to fulfill their academic potential (see Chapter 33).

Mental retardation affects ≈1-3% of children in the United States, with ~80% of these children having mild retardation. Rates are several fold higher among very-low birthweight infants. In the United States, there is substantial variation in rates of mild retardation by socioeconomic status (9-fold higher in the lowest compared to the highest socioeconomic stratum), but relatively equivalent rates of severe retardation. A similar income-related distribution is found in other countries, including some of the most impoverished countries, such as Bangladesh. Lower overall rates have been reported in some countries, including countries ranging from Saudi Arabia to Sweden to China; the difference is primarily in the prevalence of mild retardation (see Chapter 36).

Posttraumatic stress disorder (PTSD) in children remains underrecognized. PTSD can follow violent attacks and witnessed violence, sexual abuse, natural disasters, motor vehicle accidents, kidnapping, and domestic violence. Female gender, prior exposure to violence, other psychologic disturbances, and low social support are also associated with its appearance after an exposure. The prevalence of childhood PTSD varies considerably around the globe, but in children with substantial exposure to violence, the rates appear to be very high. After the attacks on the World Trade Center towers and the Pentagon in 2001, 33% of U.S. children had experienced 1 or more symptoms of PTSD. The prevalence of PTSD among children and adolescents exposed to the tsunami of 2004 were 57%, 46%, 31%, 10%, and 7% 6 wk, 6 mo, 1 year, 18 mo, and 2 yr post exposure, respectively. Children hit by the waves had significantly higher rates of PTSD.

SITUATIONAL SPECIAL-RISK POPULATIONS

Children at situational special risk have had their futures compromised by actions or policies arising from their families, schools, communities, nations, or the international community. These problems have several causes, whether the end result is homeless children, runaway children, children in foster care, or children in other disadvantaged groups.

Children in Urban Settings

Over half of the world's population is urban dwellers. Although urban settings historically have offered educational, medical, recreational, and employment opportunities, an increasing number of urban dwellers are living in marginal communities with a growing gap in access to clean water, adequate sanitation or dependable electricity as the urban population rapidly increases (Fig. 1-5). As has been seen in Port-au-Prince, Haiti, after the devastating earthquake of 2010, national disasters exact an especially high toll on children and families living in makeshift homes on lands that are not intended for housing.

Children in Poverty

Family income is central to the health and well-being of children. Children living in poor families, especially those located in poor communities, are much more likely than children living in upper- or middle-class families to experience material deprivation and poor health, die during childhood, score lower on standardized tests, be

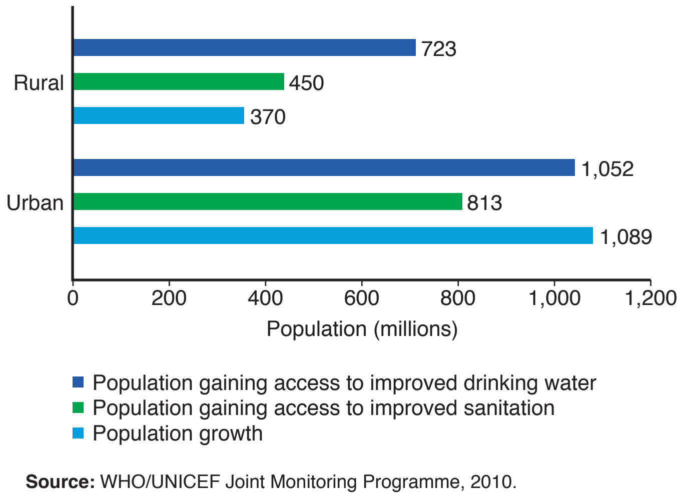

Figure 1-5 In urban areas, access to improved water and sanitation is not keeping pace with population growth. *(From UNICEF,* The state of the world's children, 2012: children in an urban world, *New York, 2012, United Nations, p. 5.)*

retained in a grade or drop out of school, have out-of-wedlock births, experience violent crime, end up as poor adults, and suffer other undesirable outcomes. As of 2010, worldwide, 22% of the population lives below the international poverty line of U.S. $1.25 per capita per day; 47% of sub-Saharan and 50% of the least-developed nations live below this amount. Poverty rates are higher for children than adults and are highest for infants and toddlers. Higher in general in developing countries, within each country, the rate of infant mortality among the poorest quintile of the population is about twice that of the wealthiest quintile (see Fig. 1-2).

In the United States, from 1990 to 2000, the percentage of children <18 yr living below the poverty line had decreased from 21% to 16%. In 2010, 2 yr after the start of the recession, the rate had risen to 22%. Black and Hispanic children consistently have had higher poverty rates than Asian and white children. In 2010, 39% of black children and 35% of Hispanic children lived in poverty, compared to 14% of Asian children and 12% of white children. Sixty-six percent of black and Hispanic children compared to only 33% of Asian and 29% of white children lived below 200% of the poverty level. Children who are poor have higher-than-average rates of death and illness from almost all causes (exceptions being suicide and motor vehicle crashes, which are most common among white, nonpoor children). Many factors associated with poverty are responsible for these illnesses: crowding, poor hygiene and healthcare, poor diet, environmental pollution, poor education, and stress.

Poverty and economic loss diminish the capacity of parents to be supportive, consistent, and involved with their children. Clinicians at all times, but especially in the context of a national or global recession, need to be especially alert to the development and behavior of children whose parents have lost their jobs or who live in permanent poverty. Fathers who become unemployed frequently develop psychosomatic symptoms, and their children often develop similar symptoms. Young children who grew up in the Great Depression in the United States and whose parents were subject to acute poverty suffered more than older children, especially if the older ones were able to take on responsibilities for helping the family economically. Such responsibilities during adolescence seem to give purpose and direction to an adolescent's life. The younger children, faced with parental depression and unable to do anything to help, suffered a higher frequency of illness and a diminished capacity to lead productive lives even as adults.

The pediatric team should ask parents about their economic resources, adverse changes in their financial situation, and the family's attempts to cope. Encouraging concrete methods of coping, suggesting ways to reduce stressful social circumstances while increasing social networks that are supportive, and referring patients and their families to appropriate welfare, job training, and family agencies can significantly improve the health and functioning of children at risk when their families live in poverty. In many cases, special services, especially social services, need to be added to the traditional medical services; outreach is required to find and encourage parents to use health services and bring their children into the healthcare system. Pediatricians also have the responsibility to contribute to, and advocate for, safety net services for impoverished children within and outside the boundaries of their own country. An increasing number of programs are available to help children of greatest need worldwide, such as Project Smile, CARE, Project Hope, and Doctors Without Borders.

Children of Immigrants and Racial Minority Groups Including U.S. Native Americans

Immigrants comprise >15% of the population in >50 countries, including many Western European countries. Thirteen percent of the U.S. population is foreign-born; 24% of all children in the United States <17 yrs have immigrant parents. The United States is experiencing a wave of immigration larger than that occurring in the early 20th century. Until the mid-20th century, emigrants to the United States were primarily white and from Europe. Such individuals now represent only approximately 10% of immigrants; the remainder are overwhelmingly of color and from throughout the world, including 29% from Mexico, 5% from China, and 4% each from India and the Philippines. Although immigrants in the United States have faced discrimination and oppression throughout history, the potential for such discrimination is compounded by the racial differences represented in the current immigrant pool. In the United States, about 240,000 children legally immigrate each year, and, through 2010, an estimated 50,000/yr entered the country illegally. In recent years the number of children from Latin American countries entering illegally has greatly increased, with estimates of more than 90,000 such children entering in 2014 alone. An estimated 5.5 million children have at least 1 illegal immigrant parent; this number doubled from 2000 to 2010.

The immigrant population constitutes a substantial proportion of the low-wage labor market. Immigrants represent 16% of all U.S. workers but 20% of low-wage workers. Immigrants are twice as likely as U.S.–born citizens to earn less than minimum wage. The poverty rate of children in immigrant families is 50% greater than in U.S.–born families; over the past decade children with 2 immigrant parents consistently have a 15% greater likelihood of living below the poverty line than children in nonimmigrant families. Contributing to the lack of access to higher salaried jobs is the lack of proficiency in English (≈52% of immigrants) and the lack of education (40% have not completed high school). Immigrants account for 29% of the uninsured in the United States.

Families of different origins obviously bring different health problems and different cultural backgrounds, which influence health practices and use of medical care. To provide appropriate services, clinicians need to understand these influences (see Chapter 4). The high prevalence of hepatitis among women from Southeast Asia makes use of hepatitis B vaccine essential for their newborns. Children from Southeast Asia and South America have growth patterns that are generally below the norms established for children of Western European origin, as well as high rates of hepatitis, parasitic diseases, and nutritional deficiencies and high degrees of psychosocial stress. Foreign-born children may surpass American-born children in some health outcomes, but their health deteriorates as they become acculturated (see Chapter 4).

Refugee children who escape from war or political violence and whose families have been subjected to extreme stress represent a subset of immigrant children who have faced severe trauma. These children have a particularly high incidence of mental and behavioral problems (see Chapter 39). Armed conflicts in 2011 resulted in an especially high (4 million) number of refugees worldwide.

Linguistically isolated households, in which no one older than 14 yr of age speaks English, often present significant obstacles to providing quality healthcare to children because of difficulties in understanding and communicating basic concerns and instructions, avoiding

compromising privacy and confidentiality interests, and obtaining informed consent (see Chapter 4).

The United States is home to multiple minority populations, including the 2 largest groups, Latinos and African-Americans. The nonwhite minority groups will constitute >50% of the U.S. population by 2050. Nonwhite children in the United States disproportionately experience adverse child health outcomes (Tables 1-3 and 1-4). Infants that are born to African-American mothers experience low birthweight and infant mortality rates twice those with white mothers (see Chapter 93). Rates of these 2 adverse health outcomes are also substantially higher among some groups of Hispanic infants and children, the rates are particularly high among those of Puerto Rican descent (≈1.5 times the rates for white infants). In 2010, the overall infant mortality rate was 6.4 per 1,000 live births, whereas that for non-Hispanic African-America infants was 11.7; for Native Americans, 8.3; and Puerto Ricans, 7.1. Mexicans, Asians, Pacific Islanders, Central and South Americans, and Cubans were below the national average. Latino, Native American, and African-American children are substantially more likely to live in poverty than are white children.

There are approximately 5.1 million Native Americans (including those with mixed races/ethnicities) and 566 federally recognized tribes. The Native American population increased by 26% from 2000 to 2010 compared to a national increase of only 9.7%. Approximately 60% of Native Americans live in urban areas, not on or near native lands. Like their minority immigrant counterparts, they have faced social and economic discrimination. The unemployment and poverty levels of Native Americans are, respectively, 3-fold and 4-fold that of the white population, and far fewer Native Americans graduate from high school or go to college. The rate of low birthweight among Native Americans is more than the white rate but less than the black rate. The neonatal and the postneonatal mortality rates are higher for Native Americans living in urban areas than for urban white Americans. Deaths in the first year of life from sudden infant death syndrome, pneumonia, and influenza are higher than the average in the United States, whereas deaths as a result of congenital anomalies, respiratory distress syndrome, and disorders relating to short gestation and low birthweight are similar.

Unintended injury deaths among Native Americans occur at twice the rate for other U.S. populations; deaths caused by malignant

Table 1-3 Deaths Rates for All Causes Among Children and Young Adults According to Sex, Race, Hispanic Origin, and Age: 2010

	Deaths Per 100,000 Resident Population			
	UNDER 1 yr	1-4 yr	5-14 yr	15-24 yr

*2009.

neoplasms are lower. During adolescence and young adulthood, suicide and homicide are the second and third causes of death in this population and occur at about twice the rates of the rest of the population. There may be significant underreporting of deaths of Native American children.

As many as 75% of Native American children have recurrent otitis media and high rates of hearing loss, resulting in learning problems. Tuberculosis and gastroenteritis, formerly much more common among Native Americans, now occur at about the national average. Psychosocial problems are more prevalent in these populations than in the general population: depression, alcoholism, drug abuse, out-of-wedlock teenage pregnancy, school failure and dropout, and child abuse and neglect.

An estimated 300 million indigenous persons live in 70 countries (50% in Asia) and speak ≈4,000 languages. Such children endure lower vaccination rates, lower school entry and higher dropout rates, higher rates of poverty, and lower access to justice. Indigenous children in Latin America account for 66% of the deaths of children younger than age 2 yr.

Children of Migrant Workers

Families facing economic hardship have been forced to leave their land and homes in search of better opportunities; such migrations are often within a country or between neighboring countries.

In the United States, the number of migrant and seasonal farm workers is estimated to exceed 3 million, with 68% born in Mexico; 52% are parents, often accompanied by their children as they travel from site to site. The families experience poor housing, frequent moves, and a socioeconomic system controlled by a crew boss who arranges the jobs, provides transportation, and often, together with the farm owners, provides food, alcohol, and drugs under a "company store" system that leaves migrant families with little money or in debt. Children often go without schooling. English skills are limited, with 35% speaking no English and 27% "a little." The average family income is $17,500 to $19,999. Only 8% report receiving health insurance.

The medical problems of children of migrant farm workers are similar to those of children of homeless families: increased frequency of infections (including HIV), trauma, poor nutrition, poor dental care, low immunization rates, exposures to animals and toxic chemicals, anemia, and developmental delays.

Homeless Children

The number of homeless children in the United States has increased by more than 35% since the recession began in 2007. An estimated 1.6 million children are homeless, living in shelters, with other relatives or on the streets.

Homeless children have an increased frequency of illness, including intestinal infections, anemia, neurologic disorders, seizures, behavioral disorders, mental illness, and dental problems, as well as increased frequency of trauma and substance abuse. Homeless children are admitted to U.S. hospitals at a much higher rate than the national average. They have higher school failure rates, and the likelihood of their being victims of abuse and neglect is much higher. The limited research on homeless children suggests high rates of developmental delays, severe depression, or learning disorders. The increased frequency of maternal psychosocial problems, especially depression, in homeless households has a significant untoward impact on the mental and physical health of these children. Because families tend to break apart under the strain of poverty and homelessness, many homeless children end up in foster care. If their families remain intact, frequent moves make it very difficult for them to receive continuity of medical care or schooling.

Provision of adequate housing, job retraining for the parents, and mental health and social services are necessary to prevent homelessness from occurring. Physicians can have an important role in motivating society to adopt the social policies that will prevent homelessness from occurring by educating policymakers that these homeless children are at greater risk of becoming burdens both to themselves and to society if their special health needs are not met.

Runaway and Thrown-Away Children

Annually in the United States, an estimated 1.6-2.8 million youth run away. Several hundred thousand of these children have no secure and safe place to stay. Black and Hispanic youth, as well as lesbian, homosexual, bisexual, and transgender youth, are disproportionately represented in these numbers. The usual definition of a *runaway* is a youth younger than 18 yr who is gone for at least 1 night from his or her home without parental permission; ~70% of these youth endangers their physical well-being during the runaway episode. Most runaways leave home only once, stay overnight with friends, and have no contact with the police or other agencies. This group is no different from their "healthy" peers in terms of psychological status. A smaller but unknown number become multiple or permanent "runners" and are significantly different from the one-time runners, with less-favorable long-term outcomes.

Thrown-aways include children told directly to leave the household, children who have been away from home and are not allowed to return, abandoned or deserted children, and children who run away but whose caretakers make no effort to recover them or do not appear to care if they return. The same constellation of causes common to many of the other special-risk groups is characteristic of permanent runaways and thrown-aways, including environmental problems (family dysfunction, abuse, poverty) and personal problems of the young person (poor impulse control, psychopathology, substance abuse, or school failure). Thrown-aways experience more violence and conflicts in their families.

In the United States, it is a minority of runaway youths who become homeless street people. These youths have a high frequency of problem behaviors, with 75% engaging in some type of criminal activity and 50% engaging in prostitution. A majority of permanent runaways have serious mental problems; more than 33% are the product of families who engage in repeated physical and sexual abuse (see Chapter 40). These children also have a high frequency of medical problems, including hepatitis, sexually transmitted infections, and drug abuse. Although runaways often distrust most social agencies, they will come to and use medical services. Medical care may become the point of reentry into mainstream society and the path to needed services. U.S. parents who seek a physician's advice about a runaway child should be asked about the child's history of running away, the presence of family dysfunction, and personal aspects of the child's development. If the youth contacts the physician, the latter should examine the youth and assess the youth's health status, as well as willingness to return home. If it is not feasible for the youth to return home, foster care, a group home, or an independent living arrangement should be sought by referral to a social worker or a social agency. Although legal considerations involved in the treatment of homeless minor adolescents may be significant, most states, through their "Good Samaritan" laws and definitions of emancipated minors, authorize treatment of homeless youths. Legal barriers should not be used as an excuse to refuse medical care to runaway or thrown-away youths.

The issue of runaway youths is very complex in many developing nations, where in many instances the youth may be orphaned and/or leaving situations of forced sex or other abusive situations. It is estimated that there are tens of millions of such youth worldwide. Natural disasters such as the 2010 earthquake devastating Haiti also contribute to growing numbers of orphaned children. In 2012, there were an estimated 17.8 million HIV orphans globally, with 14.8 > 15 million in Africa. With school attendance <50% in many parts of sub-Saharan Africa, children who are orphaned are 17% less likely to attend school. Humanitarian and international organizations have begun to focus on this very vulnerable group of youths across the globe. Rates are often uncertain, and in many countries, these children have not even been recognized as an at-risk group, so great is the social chaos and so massive are the unmet needs.

Children Directly Affected By War and Other Forms of Direct Violence

See Chapter 39.2.

There have been ~250 major wars (defined as armed combat with more than 1,000 casualties) since the end of the Second World War.

The majority of these conflicts have been civil wars, many of which have lasted longer than a decade. Sixteen of the world's poorest 20 countries have endured a civil war in the past 20 yr. Poorer countries are more likely to engage in war; a country whose median income is at the 50th percentile is one-half as likely to engage in a civil war as a country whose median income is at the 10th percentile. The distinction between intentional and unintentional injury loses its meaning in such situations; in modern wars, 70-80% of casualties are among women and children. Direct mortality and morbidity to children account for only a portion of war's destructive impact on children. In 1996 the United Nations commissioned a report addressing the full consequences of war on children entitled "Promotion and Protection of the Rights of Children: Impact of Armed Conflict on Children" including (1) the disruption of basic educational and child health pediatric care and services; (2) hardships endured as a result of refugee status; (3) the abuse of the 250,000-300,000 children younger than age 18 yr who are soldiers; and (4) the impact on children when 1 or both parents are deployed to serve.

A growing number of children worldwide are facing acts of violence with a broad reach outside of the context of war, including religious crusades (such as suicide bombers in countries not always engaged in war), countries with extraordinarily high rates of violence (such as certain cities in South Africa and Mexico) and as a result of individuals with uncertain or confused personal motives, such as the mass shooting in an elementary school in Sandy Hook, Connecticut. While the direct consequences of such nonwar violence impact far fewer children than do those from war, the reach of such random acts of violence is increasingly touching a wider swath of our globe.

Inherent Strengths in Vulnerable Children and Interventions

By age 20-30 yr, many children in the United States and other developed countries who were at special risk will have made moderate successes of their lives. Teenage mothers and children who were born prematurely or in poverty demonstrate that, by this age, the majority have made the transition to stable marriages and jobs and are accepted by their communities as responsible citizens. As the numbers of risk factors increases for an individual, the odds for a successful adulthood decline.

Certain biologic characteristics are associated with success, such as being born with an accepting temperament. Avoidance of additional social risks is even more important. Premature infants or preadolescent boys with conduct disorders and poor reading skills, who must also face a broken family, poverty, frequent moves, and family violence, are at much greater risk than children with only 1 of these risks. Perhaps most important are the protective buffers that have been found to enhance children's resilience because these can be aided by an effective healthcare system and community. Children generally do better if they can gain social support, either from family members or from a nonjudgmental adult outside the family, especially an older mentor or peer. Providers of medical services should develop ways to "prescribe" supportive "other" persons for children who are at risk. Promotion of self-esteem and self-efficacy is a central factor in protection against risks. It is essential to promote competence in some area of these children's lives.

A team is needed because it is rare for 1 individual to be able to provide the multiple services needed for high-risk children. Successful programs are characterized by at least 1 caring person who can make personal contact with these children and their families. Most successful programs are relatively small (or are large programs divided into small units) and nonbureaucratic but are intensive, comprehensive, and flexible. They work not only with the individual, but also with the family, school, community, and at broader societal levels. Introduction of remedial programs to children at the youngest possible age appears to increase the chance of success across multiple problem areas. It is also important for services to be continued over a long period.

Global Warming

Global climate change is occurring and will impact everyone; its impact will be harder felt on children and hardest felt are certain categories of vulnerable child, including those living in areas threatened by variations in rainfall, temperatures or hurricanes and cyclones (Fig. 1-6).

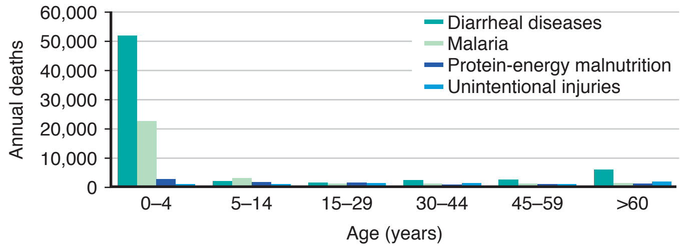

Figure 1-6 Deaths attributable to global climate change: 2004 annual data in total numbers divided by age categories. *(Data from* WHO Global burden of disease: 2004 update. *2008. Available at* http://www.who.int/healthinfo/global_burden_disease/GBD_report_2004update_full.pdf. *Image from Sheffield PE, Landrigan PJ. Global climate change and children's health: threats and strategies for prevention.* Environ Health Perspect *2011;119:291.)*

The Challenge to Pediatricians

Concerns about the aforementioned problems of children throughout the world have generated 3 sets of goals. The *first set* includes that all families have access to adequate perinatal, preschool, and family planning services; that international and national governmental activities be effectively coordinated at the global, regional, national, and local levels; that services be so organized that they reach populations at special risk; that there be no insurmountable or inequitable financial barriers to adequate care; that the healthcare of children have continuity from prenatal through adolescent age periods; and that every family ultimately have access to all necessary services, including developmental, dental, genetic, and mental health services. A *second set* of goals addresses the need for reducing unintended injuries and environmental risks, for meeting nutritional needs, and for health education aimed at fostering health-promoting lifestyles. A *third set* of goals covers the need for research in biomedical and behavioral science, in fundamentals of bioscience and human biology, and in the particular problems of mothers and children.

PATTERNS OF HEALTHCARE

Healthcare utilization and organization differs significantly among nations, reflecting differences in the geography and wealth of the country; the priority placed on healthcare versus other competing needs and interests within a nation and by the international community; philosophy regarding prevention versus curative care; and the balance between child and adult healthcare needs. An interesting analysis of 2 industrialized countries (United States and Japan) revealed that for comparable symptoms, Japanese children were 2.5 times more likely to visit a community physician's office or emergency clinic, and 11 times more likely to visit a hospital-based outpatient clinic. In most countries, hospitals are sources of both routine and intensive child care, with medical and surgical services that may range from immunization and developmental counseling to open heart surgery and renal transplantation. Clinical conditions and procedures requiring intensive care are also likely to be clustered in university-affiliated centers serving as regional resources—if these resources exist.

In developing countries, external forces may also contribute greatly to the organization of healthcare and possibly to healthcare utilization. This relationship is complex. The significant declines in infant and child mortality enjoyed in many of the developing countries in the past 4 decades have occurred in the context of support from the international community, including agencies such as UNICEF, WHO, and the World Bank; bilateral donors (the aid provided from 1 country to another); and nongovernmental agencies to develop integrated, universal primary pediatric care with an emphasis on primary (vaccination) and selected secondary (oral rehydration solution [ORS], treatment of pneumonia and malaria) prevention strategies. But, as

healthcare systems become dependent on such external support, their populations are increasingly vulnerable to changes in political will over which they have little or no influence.

In the United States, pediatricians report an average of 50 preventive care visits per wk, 33% for infants. The visits average 17-20 min, increasing in length as children become adolescents. The principal diagnoses, accounting for ≈40% of these visits, are well-child visits (15%), middle-ear infections (12%), and injuries (10%). Ambulatory visits by children and youth decrease with age. The opposite occurs with adults. Nonwhite children are more likely than white children to use hospital facilities (including the emergency room) for their ambulatory care; the number of well-child visits annually is almost 80% higher among white infants than black infants. Children with private insurance are more likely than children with public insurance who, in turn, are more likely than uninsured children to receive non–emergency room care. Insurance coverage increases outpatient utilization and receipt of preventive care by approximately 1 visit per year for children. Between 70 and 90 children per 1,000 children are hospitalized per year. These rates are less than those of adults up to age 65 yr, except for the first year of life. Children represent <7% of the total acute hospital discharges; in children's hospitals, ≈70% of admissions are for chronic conditions, and 10-12% of pediatric hospitalizations are related to birth defects and genetic diseases. White children are less likely to be hospitalized than black or Hispanic children, but more likely than Asian children. Poor children are nearly twice as likely as nonpoor children to be hospitalized. Insurance coverage also appears to reduce hospital admissions that are potentially manageable in an ambulatory setting.

PLANNING AND IMPLEMENTING A SYSTEM OF CARE

Access to at least a basic level of quality services to promote health and treat illness is a right of every person. Having health insurance, whether private or governmental, is strongly associated with access to primary care. Efforts to make the delivery of healthcare more efficient and effective have led to the creation of new categories of healthcare providers, such as pediatric nurse practitioners in industrialized nations and trained birth attendants in developing countries, and to participate in new organizations for providing care to children, such as various managed care arrangements.

The U.S. Patient Protection and Affordable Care Act passed in 2010 and upheld by the United States Supreme Court in 2012, contains provisions specific to children, including a requirement that all preexisting conditions be covered and (effective 2014) pregnancy and newborn care be covered, as well as vision and dental care for children.

Health Services for At-Risk Populations

In the United States, the largest vulnerable group is children living in poverty, representing approximately 22% of U.S. children. Substantial proportions of children in other industrialized countries are also living in poverty. The approach to addressing the needs of this group in the United States has been the establishment of a targeted insurance program, Medicaid, which became law in 1965 as a jointly funded cooperative venture between the federal and state governments to assist states in the provision of adequate medical care to eligible needy persons. The federal statute identifies >25 different eligibility categories for which federal funds are available. These statutory categories can be classified into 5 broad coverage groups: children, pregnant women, adults in families with dependent children, individuals with disabilities, and individuals ≥65 yr old. Pediatric care in the United States is highly dependent on Medicaid; however, only a relatively small proportion of the Medicaid funds actually go to child healthcare, with the remainder serving older adults. Following broad national guidelines, each state establishes its own eligibility standards; determines the type, amount, duration, and scope of services; sets the rate of payment for services; and administers its own program. Although Medicaid has made great strides in enrolling low-income children, significant numbers of children remain uninsured. From 1988 to 1998, the proportion of children insured through Medicaid increased from 15.6% to 19.8%, but the percentage of children without health insurance increased from 13.1% to 15.4%. Minority children were disproportionately among those without insurance. The Balanced Budget Act of 1997 created a new children's health insurance program called the State Children's Health Insurance Program (SCHIP). This program gave each state permission to offer health insurance for children, up to age 19 yr, who are not already insured. SCHIP is a state-administered program and each state sets its own guidelines regarding eligibility and services. There is great variation by state, but in many states, the SCHIP program has begun to reduce racial inequities in access to healthcare for children. In 2009, the percent of children without insurance had decreased to 9%.

Many industrialized nations have adapted different "safety net" systems to assure adequate coverage of all youth. Many of these programs provide health insurance for all children, regardless of income, hoping to avoid problems with children losing insurance coverage and access to healthcare as a result of changes in eligibility by providing a single form of insurance that all providers accept. The response of developing countries to the issue of universal access to care for children has been uneven, with some providing no safety net, but many having limited universal or safety net services.

To address the special needs of Native Americans in the United States, the Indian Health Service, established in 1954, has been the responsibility of the Public Health Service, but the 1975 Indian Self-Determination Act gave tribes the option of managing Native American health services in their communities. The Indian Health Service is managed through local administrative units, and some tribes contract outside the Indian Health Service for healthcare. Much of the emphasis is on adult services: treatment for alcoholism, nutrition and dietetic counseling, and public health nursing services. There are also >40 urban programs for Native Americans, with an emphasis on increasing access of this population to existing health services, providing special social services, and developing self-help groups. In an effort to accommodate traditional Western medical, psychologic, and social services to the Native American cultures, such programs include the "Talking Circle," the "Sweat Lodge," and other interventions based on Native American culture (see Chapter 4). The efficacy of any of these programs, especially those to prevent and treat the sociopsychological problems particular to Native Americans, has not been determined.

Recognizing the health needs of migrants in the United States, the U.S. Public Health Service initiated in 1964 the Migrant Health Program to provide funds for local groups to organize medical care for migrant families. Many migrant health projects that were initially staffed by part-time providers and were open for only part of the year have been transformed into community healthcare centers that provide services not only for migrants but also for other local residents. As of 2012, there are >700 Migrant Health Centers and satellite sites operating in 42 states. Health services for migrant farm workers often need to be organized separately from existing primary care programs because the families are migratory. Special record-keeping systems that link the healthcare provided during winter months in the south with the care provided during the migratory season in the north are difficult to maintain in ordinary group practices or individual physicians' offices. Outreach programs that take medical care to the often remote farm sites are necessary, and specially organized Head Start, early education, and remedial education programs should also be provided. Approaches in other countries have also focused on business initiatives for migrant populations to enable them to overcome the cycle of financial dependency on their migratory lifestyle.

The United States has spent >$14 billion through the 1987 McKinney-Vento Act to provide emergency food, shelter, and healthcare; to finance help for young runaways; to aid homeless people in making their way back into the housing market; and to place homeless children in school. Mobile vans, with a team consisting of a physician, nurse, social worker, and welfare worker, have been shown to provide effective comprehensive care, ensure delivery of immunizations, link the children to school health services, and bring the children and their families into a stable relationship with the conventional medical system. Special record-keeping systems have been introduced to enhance continuity and to provide a record of care once the family has moved to a

permanent location. Because of the high frequency of developmental delays in this group, linkage of preschool homeless children to Head Start programs is an especially important service. The Runaway Youth Act, Title III of the Juvenile Justice and Delinquency Prevention Act of 1974 (Public Law 93-414) and its amended version (Public Law 95-509) have supported shelters and provide a toll-free 24 hr telephone number (1-800-621-4000) for youths who wish to contact their parents or request help after having run away.

Other nations have expanded the reality of the "health safety net" for children. In Belgium, Finland, the Netherlands, Portugal, and Spain, the right to housing has been incorporated into the national constitutions. The Finnish government has devised a multifaceted response to the problem, including house building, social welfare and healthcare services, and the obligation to provide a home of minimum standards for every homeless person. The number of homeless in Finland has been reduced by 50%.

Evaluation of Healthcare

The Institute of Medicine issued a report, "Crossing the Quality Chasm: A New Health System for the 21st Century" in 2001. This report, challenging American physicians to renew efforts to focus not just on access and cost, but also on quality of care, has been furthered in several pediatric initiatives, including, but not limited to, specific initiatives for monitoring child health outlined in the Institute of Medicine report "Children's Health, the Nation's Wealth"; challenge/demonstration grants funded by the Robert Wood Johnson Foundation; and the National Initiative for Children's Healthcare Quality. Importantly, each of these initiatives is calling for the establishment of measurable standards for assessment of quality of care and for the establishment of routine plans for periodic reassessment thereof. Efforts have been initiated at some medical centers to establish evidence-based clinical pathways for disorders (such as asthma) where there exists sound evidence to advise these guidelines. Pediatricians have developed tools to evaluate the content and delivery of pediatric preventive "anticipatory guidance," the cornerstone of modern pediatrics (see Chapter 5).

THE INFORMATION EXPLOSION OF THE 21ST CENTURY

There is no touchstone through which physicians can ensure that the process of their own continuing education will keep them abreast of advancing knowledge in the field, but the requirement for "Maintenance of Certification" as opposed to the former practice of lifelong certification by specialty boards actively addresses this issue (see Chapter 2). An essential element of this process may be for physicians to take an active role, such as participating in medical student and resident education. Efforts in continuing self-education will also be fostered if clinical problems can be made a stimulus for a review of standard literature, alone or in consultation with an appropriate colleague or consultant. This continuing review will do much to identify those inconsistencies or contradictions that will indicate, in the ultimate best interest of patients that things are not what they seem or have been said to be. These difficulties may be exacerbated by commercially sponsored education programs and research projects that may, on occasion, put profit before the patient's best interests. Physicians still learn most from their patients, but this will not be the case if they fall into the easy habit of accepting their patients' problems casually or at face value because the problems appear to be simple.

The tools that physicians must use in dealing with the problems of children and their families fall into 3 main categories: *cognitive* (up-to-date factual information about diagnostic and therapeutic issues, available on recall or easily found in readily accessible sources, and the ability to relate this information to the pathophysiology of their patients in the context of individual biologic variability), *interpersonal or manual* (the ability to carry out a productive interview, execute a reliable physical examination, perform a deft venipuncture, or manage cardiac arrest or resuscitation of a depressed newborn infant), and *attitudinal* (the physician's unselfish commitment to the fullest possible implementation of knowledge and skills on behalf of children and their families in an atmosphere of empathic sensitivity and concern). With regard to this last category, it is important that children participate with their families in informed decision making about their own healthcare in a manner appropriate to their stage of development and the nature of the particular health problem.

The workday needs of professional persons for knowledge and skills in care of children vary widely. Primary care physicians need depth in developmental concepts and in the ability to organize an effective system for achieving quality and continuity in assessing and planning for healthcare during the entire period of growth. They may often have little or no need for immediate recall of esoterica. On the other hand, consultants or subspecialists not only need a comfortable grasp of both common and uncommon facts within their field and perhaps within related fields, but also must be able to cope with controversial issues with flexibility that will permit adaptation of various points of view to the best interest of their unique patient.

At whatever level of care (primary, secondary, or tertiary) or in whatever position (student, pediatric nurse practitioner, resident pediatrician, practitioner of pediatrics or family medicine, or pediatric or other subspecialist), professional persons dealing with children must be able to identify their roles of the moment and their levels of engagement with a child's problem; each must determine whether his or her experience and other resources at hand are adequate to deal with this problem and must be ready to seek other help when they are not.

ORGANIZATION OF THE PROFESSION AND THE GROWTH OF SPECIALIZATION

The 20th century witnessed the formation of professional societies of pediatricians around the globe. Some of these societies, such as the European Board of Pediatrics and the American Board of Pediatrics, are concerned with education and the awarding of credentials certifying competence and the continuing maintenance of competence as a pediatrician and/or a pediatric subspecialist to the public. From its inception in 1933 through the beginning of 2014, the American Board of Pediatrics certified 108,879 general pediatricians.

The amount of information relevant to child healthcare is rapidly expanding, and no person can become master of it all. Physicians are increasingly dependent on one another for the highest quality of care for their patients. Approximately 25% of pediatricians in the United States claim an area of special knowledge and skill, including >20,000 who have board certification in 1 of the 14 pediatric subspecialties with board certification. Each year approximately 10% of the ≈3,000 pediatric residents training in the United States are enrolled in a dual-residency training program that will lead to eligibility for board certification in both pediatrics and internal medicine.

In the United States, most subspecialists practice in academic settings or children's hospitals. Likewise, specialists are growing in number in other industrialized countries and in developing nations that are becoming industrialized. Reflecting the diverse cultures, organization of medical care, economic circumstances and the history of medicine within each of the ~200 countries across the globe, is the great diversity in role of pediatricians within the healthcare delivery system to children in each country; Figure 1-7 illustrates the resultant variations in pediatricians per population among some European countries.

Beyond certifying bodies, there are other pediatric societies primarily concerned with organizing members of the profession in their country or region to dedicate their efforts, advocacy and resources toward children. In the United States, the American Academy of Pediatrics currently has a membership of ≈60,000 child health specialists in both academic and private practice. Most general pediatricians in the United States enter private practice; ≈66% are in group practices, 5% enter solo practice, and 5% work in a health maintenance organization. The American Academy of Pediatrics provides a variety of continuing educational services to pediatricians in multiple national and regional settings and tracks the professional activities and practices of its members. A comparable group in India, the Indian Academy of Pediatrics, was formed in 1963, and now has ~16,500 members and 16 subspecialty chapters. Likewise, the Pakistani Pediatrics Association was founded in 1967, the Malaysian

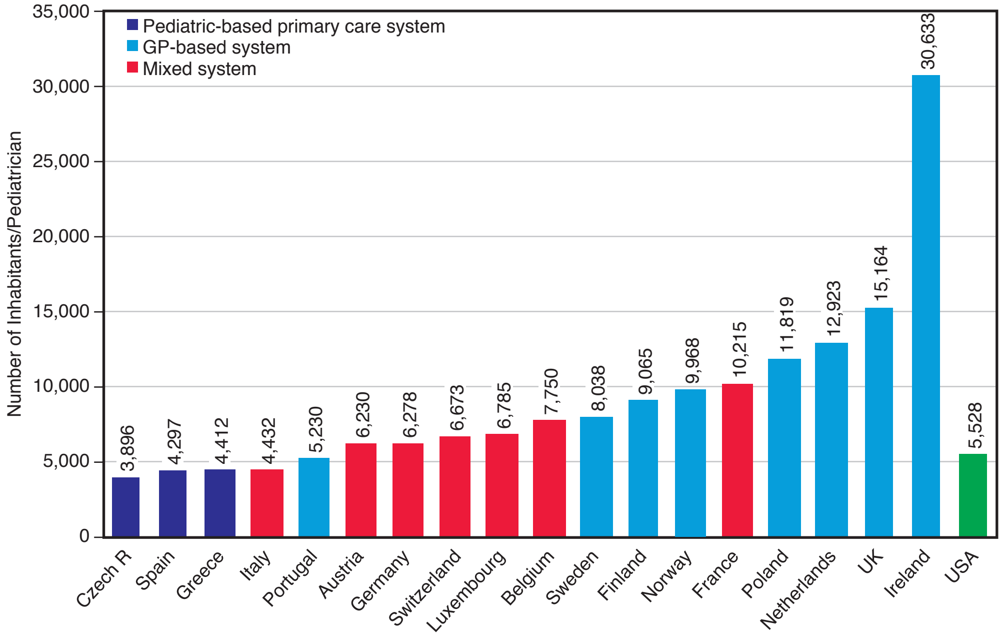

Figure 1-7 Number of inhabitants per pediatrician in some European countries as a function of the differences in primary health care delivery systems, population, and pediatric work force, compared to the current situation in the United States. *(Courtesy of Dr. Alfred Tenore, European Academy of Paediatrics and Chair of Global Pediatric Education Consortium.)*

Pediatric Association was started in 1985, and the Canadian Pediatric Society was founded in 1922. Established in 1974, the Asian Pacific Pediatric Association includes 20 member pediatric societies from throughout eastern Asia, and the International Pediatric Association established in 1910 includes 144 national pediatric societies from 139 countries, 10 regional pediatric societies, and 11 international pediatric specialty societies. The European Academy of Pediatrics is the pediatric specialist organization for the member countries of the European Union and the European Free Trade Association, and the Pediatric Council of the Arab Board of Medical Specializations is the comparable institution for 19 of the world's Arab nations These societies represent but a few of the many national and regional pediatric professional organizations around the world who seek to identify and bring treatments and approaches supporting child well-being to pediatricians worldwide.

Bibliography is available at Expert Consult.

1.1 Innovations in Addressing Child Health and Survival in Low-Income Settings

Zulfiqar Ahmed Bhutta

GLOBAL BURDEN AND MORTALITY TRENDS

The current global burden of neonatal and child death is largely concentrated in Central and sub-Saharan Africa and South Asia (Figs. 1-8 and 1-9; see also Fig. 1-1 and Table 1-1). Ten countries have almost ⅔ of the global burden of maternal and newborn deaths as well as stillbirths.

It is estimated that 6.2 million children younger than 5 yr died in 2012, a 63% reduction from 16.9 million in 1970. However, there are still wide disparities and in 2012, child mortality rates range from a high of 182 per 1,000 in Sierra Leone to 2 per 1,000 in Iceland and Luxembourg. Progress in this regard has been variable, and despite global progress, of the 75 countdown countries that have almost 98% of all maternal and under-5 child deaths, only 13 are on track to reach MDG targets for child mortality. Other global estimates from the Institute of Health Metrics and Evaluation indicate that only 31 developing countries will reach MDG 4 targets by 2015.

From 1990 to 2013, annual rates of decline ranged from 6.7% to –0.9%. In 2013, neonatal deaths account for 41.3% of under-5 deaths, up from 37.6% in 1990. Comparing 2013 with 1990, rising numbers of births, particularly in sub-Saharan Africa, were associated with an additional 1.5 million child deaths. Neonatal mortality reduction has been much slower than that for maternal and child (1-59 mo) mortality, and slowest in the highest burden countries, especially in Africa. The sobering realization is that even in countries that would reach their MDGs 4 and 5 targets, many would still have high numbers of deaths with much scope for improvement.

CAUSES OF NEWBORN AND CHILD DEATHS

The Child Health Epidemiology Reference Group estimated that 40.3% of 7.6 million under-5 deaths in 2010 occurred in the newborn period; 2013 figures from the Institute of Health Metrics and Evaluation corroborate these estimates.

Among newborn deaths, major causes include preterm birth complications (14.1%; 1.078 million), intrapartum-related complications, previously labeled as birth asphyxia (717,000 deaths; 9.4%), and sepsis or meningitis (393,000; 5.4%) neonatal deaths. Among older children, the leading causes of deaths included pneumonia (14.1%; 1.071 million), diarrhea (9.9%; 751,000), and malaria (7.4%; 564,000) (Fig. 1-10*A*). Existing data suggest broadly comparable figures for under-5 deaths (Fig. 1-10*B*), although some categories are different, notably higher proportion of malaria deaths among under-5 children in the Global Burden of Disease study 2010 estimates and lower numbers for pneumonia deaths.

An unaddressed burden of stillbirths exists globally and is not included in the current Global Burden of Disease study estimates. Of an estimated 2.64 million stillbirths worldwide in 2009, 76.2% occurred in south Asia and sub-Saharan Africa, mostly among rural populations. An estimated 45% of these stillbirths occur in the intrapartum period, reflecting a clear extension of the neonatal deaths related to intrapartum events, previously labeled as birth asphyxia deaths. The highest risk time is around birth, when more than 40% of maternal deaths and combined stillbirths during labor and neonatal deaths occur. These deaths occur rapidly, requiring urgent response by healthcare workers. Table 1-5 lists the top 10 countries for risks of intrapartum stillbirths and newborn deaths on the first day of life.

Being born small, because of preterm birth or small for gestational age (SGA) or both, is the leading risk factor for neonatal deaths and carries increased risk for postneonatal mortality, growth failure, and adult-onset noncommunicable conditions (see Chapter 97). South Asia has the highest SGA rates and sub-Saharan Africa has the highest preterm birth rates. Babies who are term SGA low birthweight face risks for stunting, and adult-onset metabolic conditions. Fifteen million preterm births, especially those <32 wk gestation, are at highest risk of neonatal death, with ongoing postneonatal mortality risk, significant risk of long-term neurodevelopmental impairment, and stunting, as well as noncommunicable conditions. Four million neonates annually have other life-threatening conditions, including intrapartum-related

Angola	16	11.7	27.4

brain injury, severe bacterial infection, and pathologic jaundice, with 1.4 million neonates surviving with long-term neurodevelopmental impairment. The consequences of not acting to improve birth outcomes by 2035 are estimated at 116 million deaths, 99 million with disability or lost development potential, and many millions of adults with noncommunicable disease following being born SGA and or prematurely.

UNDERSTANDING SOCIAL DETERMINANTS AND BARRIERS FOR CARE

Understanding the causes of deaths allows for better planning and targeting of interventions. Between 2000 and 2010, the bulk of the reduction in under-5 child mortality related to decreases in pneumonia, measles, and diarrhea deaths, whereas corresponding reductions in neonatal causes of deaths other than tetanus (notably those associated with prematurity and intrapartum related events) was minimal.

Poverty is a huge barrier and affects all levels of care because much of the burden of maternal and child mortality and ill health is concentrated among the poorest countries of sub-Saharan Africa and South Asia. In many of these countries, the bulk of the mortality is clustered among the poor, frequently residing in remote and rural populations with limited access to healthcare services. A sizeable proportion of deaths also occur among the urban poor living in slum conditions with limited social support networks and poor living conditions. Other determinants, such as environmental factors (e.g., overcrowding, poor air quality and sanitary conditions), may be much worse in urban slums than in many rural populations. Lack of trained human resources and transportation facilities in rural populations, as well as quality of care in existing primary care settings are also problems. Figures 1-11 and 1-12 illustrate some of the inequities observed across key evidence-based maternal and child interventions across and within large number of developing countries. Interventions that have a relatively narrow

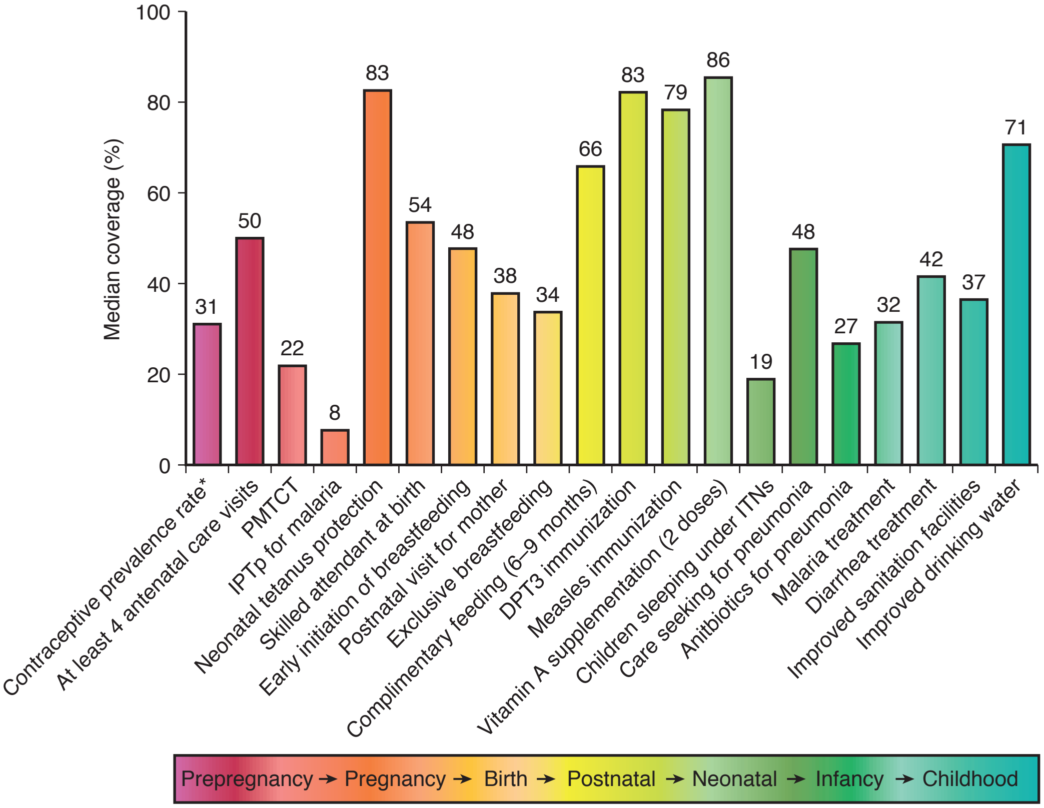

Figure 1-11 Global coverage for 75 countdown countries with 98% of maternal and child deaths. *(From Bhutta ZA, Chopra M, Axelson H, et al: Countdown to 2015 decade report [2000–10]: taking stock of maternal, newborn, and child survival. Lancet 375:2032–2044, 2010, Fig. 2.)*

delivery channel and mandates such as immunizations do achieve high coverage, whereas those that require functional health systems and facilities, such as skilled birth attendance and postnatal care, hardly reach half of the population in need. For others, such as the appropriate use of zinc, ORS, and antibiotics for the treatment of childhood diarrhea or pneumonia, current coverage rates are very low.

Estimates of the impact of various factors on child survival between 1990 and 2013 indicate that while rising numbers of births, particularly in sub-Saharan Africa, led to 1.5 million more child deaths, rising income per capita and maternal education led to 774,000 and 2.4 million fewer deaths, respectively. Technology change alone led to 4.0 million fewer deaths. In 23 developing countries, there is evidence that declines since 2000 have been faster than predicted on the basis of income, education, and technology shift alone.

EVIDENCE-BASED INTERVENTIONS AND INNOVATIONS TO ADDRESS INEQUITIES

There is a range of preventive, promotive and therapeutic interventions that can affect newborn and child survival (Table 1-6).

These services require **appropriate delivery platforms** for scaling up coverage, especially in circumstances where there is widespread **shortage of health workers**, and the **removal of financial barriers** that preclude care seeking and access where such care is not freely available within the public health system. There is also the need to **improve quality of care** within facilities and ensure availability of life saving commodities by well trained and motivated care providers.

COMMUNITY HEALTH WORKERS FOR NEWBORN AND CHILD HEALTH

The global shortage of a skilled health work force has been a key barrier to effective coverage and in many instances policy makers and planners resort to the use of community health workers (CHWs) who are provided basic training in preventive and promotive strategies. Such task-shifting strategies have been shown to yield beneficial results in diverse settings, frequently in malaria and HIV management. Communities should take active part in improving their own health, and the dynamic role of CHWs in delivery of health-related care are well recognized. CHWs work in liaison with frontline health workers and are fastened across the primary healthcare for better success in reaching the goals (Fig. 1-13).

A growing array of interventions delivered by CHWs can significantly improve neonatal and child health and survival; behavioral interventions to promote healthy behavior; preventive interventions, such as immunization; and more complex tasks, such as case management of childhood illnesses (e.g., pneumonia, malaria, and neonatal sepsis). The active involvement and empowerment of communities through CHWs have positive effects on health by changing health beliefs and improving care seeking for illnesses. CHWs increase the proportion of people who receive healthcare and increase the number of children with up-to-date immunization statuses. CHWs who provide some amount of support of breastfeeding, as well as care during pregnancy, help reduce child mortality through various antenatal interventions, including pregnancy surveillance, vitamin supplementation, and promotion of birth preparedness. CHW programs are also dependent upon basic tool kits and a steady and reliable supply of key commodities. Lack of adequate supplies and frequent stock outs are a major impediment to effective programs and implementation.

Women's and community support groups which are largely formulated and facilitated by CHWs have shown reductions in neonatal mortality and morbidity and improvement in domiciliary practices, such as early initiation of breastfeeding and healthcare seeking for their illnesses. These participatory activities empower mothers, emphasize safe delivery practices and encourage care seeking behavior.

Home visits by CHWs may improve coverage of key newborn care practices such as early initiation of breastfeeding, exclusive breastfeeding, skin-to-skin contact, delayed bathing and attention to hygiene, such as hand washing with soap and water, clean umbilical cord care, immunization and early diagnosis, detection of complications,

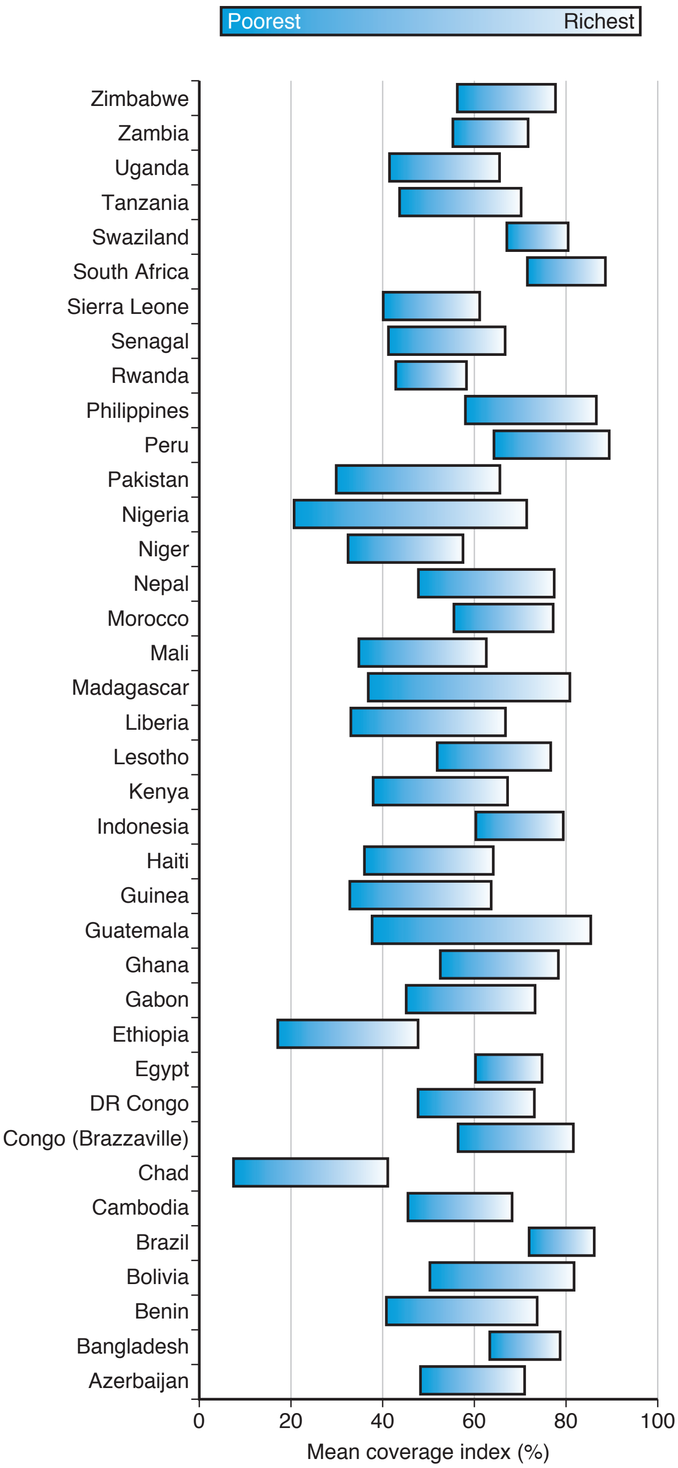

Figure 1-12 Inequities in maternal and child interventions from 38 countdown countries. *(From Bhutta ZA, Chopra M, Axelson H, et al: Countdown to 2015 decade report [2000–10]: taking stock of maternal, newborn, and child survival. Lancet 375:2032–2044, 2010,Fig. 7.)*

and appropriate referrals. Home-based newborn care consisting of therapeutic interventions, case management and referrals, and preventive interventions such as health education have shown reductions in neonatal mortality and in stillbirths.

Implementation of an essential newborn care package along with administration of home-based antibiotic therapy for suspected neonatal sepsis by CHWs has resulted in a 62% reduction in the neonatal mortality rate when 93% of the newborns in the intervention area were provided treatment. In a meta-analysis of trials of community-based case-management of pneumonia all-cause neonatal mortality was 27% lower in the intervention group, whereas pneumonia-specific neonatal mortality in the intervention group was reduced by an even greater amount. Case management of children suffering from pneumonia, malaria, and diarrhea may be the potential way forward in the low-income setting. Case management of pneumonia by CHWs could result in a 70% reduction in mortality from pneumonia in children <5 yr of age. Community-based interventions correlate to a 13% and 9% increase in care seeking for pneumonia and diarrhea, respectively. Case management is associated with increased uptake of ORS and zinc for management of diarrhea. These interventions also lead to a 32% reduction in pneumonia-specific mortality. CHWs can also be trained to perform rapid diagnostic tests for malaria, and manage test-positive children with antimalarials.

CHWs can also play a role in improving the use of anthelminthics in children. Interventions such as preventive chemotherapy, health education to promote general hygiene and sanitation, iron and β-carotene supplementation, construction of latrines, removing cattle from residential areas, staff training and community mobilization can have significant impacts on prevention and management of worm infestations. Evidence suggests that school-based delivery of anthelminthics can significantly reduce soil-transmitted helminthes prevalence, schistosomiasis prevalence, and anemia. Interventions related to handwashing counseling (for individuals or groups) suggested a 30% reduction in the risk of diarrhea as well.

THE ROLE OF INFORMATION TECHNOLOGY AND mHEALTH PLATFORMS

Mobile health, or mHealth, is the use of mobile information and communication technologies for improving health. It can be used for a wide range of purposes, including health promotion and illness prevention, healthcare delivery, training and supervision, electronic payments, and information systems. This is widely regarded as a great equalizer across social strata in increasing access to information and empower health workers to reach marginalized populations. In the simplest forms SMS/text-based campaigns can be an effective way to share health information with people who lack reliable Internet access and in other instances telemedicine can permit specialist access and consultations which were hitherto not possible because of geographic constraints and limitations. mHealth is of particular interest in low- and middle-income countries, where widespread mobile networks and access to devices are connecting people, leap-frogging older technologies to dramatically improve information flow, data collection, social and behavior change, and emergency response.

CASH TRANSFERS TO REDUCE POVERTY BARRIERS AND IMPROVE CHILD HEALTH

Out of pocket expenses by households form the major share of total health expenditure in most low income countries and a substantial share in middle income countries. Financial incentives are becoming widely used to improve healthcare coverage, alleviate poverty and improve access to child health services. Some support platforms have a dual purpose of reducing financial barriers and also strengthening service delivery. Financial incentive programs may include conditional/unconditional cash transfers, conditional/unconditional microcredit, conditional/unconditional voucher, user fee removal and health insurances. Financial incentive programs targeting child health generally focus on breastfeeding practices; vaccination; healthcare use; management of diarrheal diseases; and other preventive health interventions including preventive deworming, vitamin A and iron supplementation. These programs are also directed toward education improvement by improving school enrollment, attendance, and occasionally some measure of performance.

OTHER TECHNOLOGIES AND INNOVATIONS

There has been a massive increase in global knowledge and potential of low-cost technologies to improve diagnosis and care of sick newborn infants and children. These span bedside tools to assess risk of severe

illness such as handheld pulse oximetry devices for children with respiratory infections, development of 4% chlorhexidine gel for prevention of cord infections in newborns, and injection devices to aid health workers such as Uniject systems.

There has been considerable work to achieve consensus across a range of UN agencies, academic bodies, and professional groups on key essential evidence-based interventions for maternal and child health that need implementation and scaling up within health systems.

Chapter 2

Quality and Safety in Healthcare for Children

Ramesh C. Sachdeva

THE NEED FOR QUALITY IMPROVEMENT

There is a significant quality gap between known, recommended evidence-based care and the actual care that is delivered. Adults receive recommended care slightly higher than 50% of the time, whereas children receive recommended care only approximately 46% of the time. This quality gap exists because of a chasm between knowledge and practice—a chasm made wider by variations in practice and disparities in care from doctor to doctor, institution to institution, geographic region to geographic region, and socioeconomic group to socioeconomic group.

Historically, success in medicine was viewed as advances in technology, identification of new treatments, and the generation of new evidence to improve care. Although these facets of medical advances continue to be important, it is estimated that it takes about 17 yr for new knowledge and research findings to be adopted into clinical practice. Further, the Institute of Medicine's (IOM) report, "To Err is Human: Building a Safer Health System," highlights that ~44,000-98,000 patients die in U.S. hospitals each year because of preventable medical errors. These errors were more likely to occur in environments such as operating rooms, emergency departments, and intensive care units. Preventable medical errors have an economic cost of $17-$29 billion per year. These gaps in quality and related high costs will only be solved when physicians and healthcare systems adopt the emerging new science of **Quality Improvement (QI).**

The need for QI is expanding even further. With the growing concerns of healthcare costs and also the implementation of the Affordable Care Act, the scope of QI has expanded from the level of individual patients to include the notion of the **Triple Aim** proposed by the Institute for Healthcare Improvement–improving the care for *individual patients*, improving the care *for populations*, and improving the *cost effectiveness for healthcare delivery*. Recently, there has been a recognition that QI needs to shift from the sphere of process improvement toward outcomes improvement, and to ensure value from the standpoint of the patient.

WHAT IS QUALITY?

The IOM defines quality of healthcare as the degree to which healthcare services for individuals and populations increases the likelihood of desired health outcomes and are consistent with current professional knowledge. This definition incorporates 2 key concepts related to healthcare quality: the direct relationship between the provision of healthcare services and health outcomes, and the need for healthcare services to be based on current evidence.

To measure healthcare quality, the IOM has identified Six Dimensions of Quality all of which relate to quality of care. The Six Dimensions of Quality are **effectiveness, efficiency, equity, timeliness, patient safety,** and **patient-centered care.** Quality of care needs to be effective, which means that healthcare services should result in benefits and outcomes. Healthcare services also need to be efficient, which incorporates the idea of avoiding waste and improving system cost efficiencies. Healthcare quality should improve patient safety, which incorporates the concept of patient safety as one of the key elements within the Six Dimensions of Quality. Healthcare quality must be timely, thus incorporating the need for appropriate access to care. Healthcare quality should be equitable, which highlights the importance of minimizing variations as a result of ethnicity, gender, geographic location, and socioeconomic status. Healthcare quality should be patient-centered, which underscores the importance of identifying and incorporating individual patient needs, preferences, and values in clinical decision making.

The IOM framework of the Six Dimensions of Quality emphasizes the concept that all Six Dimensions of Quality need to be met for the provision of high quality healthcare. These concepts can be viewed as the overall *value* proposition—that is, the value created for a patient. From the standpoint of the practicing physician, these Six Dimensions of Quality can be categorized into clinical quality and operational quality. To provide high-quality care to children, both aspects of quality—clinical and operational—must be met. Historically, physicians have viewed quality to be limited in scope to clinical quality with the goal of improving clinical outcomes, and have considered efficiency optimization and access as the role of healthcare plans, hospitals, and insurers. Healthcare organizations, which are subject to regular accreditation requirements, viewed the practice of clinical care delivery as the responsibility of physicians and limited their efforts to improve quality largely to process improvement to enhance efficiencies. This is further magnified as many office-based pediatricians have independent clinical practices and interact with hospitals only when they care for hospitalized children.

This traditional perspective is changing. The evolving healthcare system requires physicians, healthcare providers, healthcare organizations, and hospitals to partner together to measure, demonstrate, and improve the overall quality of care to the patients they serve. With many regulatory and accreditation changes such as **Maintenance of Certification (MOC)** requirements of the **American Board of Pediatrics** and the planned Maintenance of Licensure by U.S. state licensing bodies, physicians will be required to understand and implement QI principles into their clinical practice and report the quality of their care delivered by them in a transparent manner.

The recently implemented Patient Protection and Affordable Care Act has at its core quality measurement and QI. The Affordable Care Act aims at enhancing access to care which is a quality dimension. Quality measurement is integral to ensuring transparency and choice across health plans. An important concept for quality within the Affordable Care Act relates to expanding the conventional scope of quality to population health.

Definitions of Quality-Related Terms

Quality includes many concepts—quality measurement, quality reporting and benchmarking, process improvement, performance, and outcomes improvement using quality initiatives (Table 2-1).

FRAMEWORK FOR QUALITY

Quality is broader in scope than QI. As adopted by the *American Academy of Pediatrics*, the approach to quality includes 4 building blocks (Fig. 2-1). First, the standard for quality must be defined (i.e., developing evidence based guidelines, best practices, or policies that guide the clinician for the specific clinical situation). These guidelines should change based upon new evidence. For example, in 2000-2001, the American Academy of Pediatrics had published guidelines for care

Table 2-1 Definitions of Quality-Related Terms

Term	Definition
Quality	"…the degree to which health services for individuals and populations increase the likelihood of desired health outcomes and are consistent with current professional knowledge." *U.S. Institute of Medicine*
Quality Initiative	"…systematic, data-guided activities designed to bring about immediate improvements in healthcare delivery in particular settings." *Hastings Center*
Performance Measure	"…yardsticks by which all healthcare providers and organizations can determine how successful they are in delivering recommended care and improving patient outcomes." *U.S. Institute of Medicine*
Performance Management	"…a systematic process by which an organization involves its employees in improving the effectiveness of the organization and achieving the organization's mission and strategic goals. By improving performance and quality, public health systems can save lives, cut costs, and get better results by managing performance." *Public Health Foundation*
Process Improvement	"… the systematic approach to closing of process or system performance gaps through streamlining and cycle time reduction, and identification and elimination of causes of below specifications quality, process variation, and non–value-adding activities." *BusinessDictionary.com*

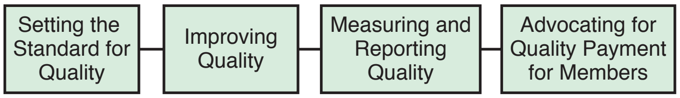

Figure 2-1 The American Academy of Pediatrics model for quality.

of children with attention-deficit/hyperactivity disorder. Subsequently, in 2011, these were updated to highlight a greater emphasis on behavioral interventions rather than pharmacologic options. Second, quality needs to be improved to close the quality gap. The quality gap refers to the difference between the recommended care and the actual care delivered to a patient. This can be achieved by using principles from improvement and implementation science. Improvement science relates to the methods and tools for achieving change. Methods can include learning collaboratives where groups of individuals share their experiences creating a community of learners. With the growth of new technology, including social media, virtual collaboratives are increasingly gaining popularity. Tools for QI can include techniques such as the Improvement Model, LEAN, Six Sigma, and Management Sciences. Implementation science is different than improvement science and relates to the study of methods to successfully spread the improvement to new settings and sustain it in these settings. Third, quality needs to be measured. Quality measures can be developed as measures for accountability and measures for improvement. Accountability measures are developed with a high level of demonstrated rigor as these are used at the macro level for measuring the quality of care at the state level, and for regional use by health plans and health systems. Efforts are ongoing to link such measures to *pay-for-performance (P4P)* for reimbursement at the hospital and individual physician level. In contrast, improvement measures are metrics that can demonstrate the improvement accompanying a QI initiative. These need to be locally relevant and typically have not had rigorous field testing. Finally, the quality measurement effort has to be linked to advocacy. Advocacy should be aimed at ensuring that there is adequate investment in early childhood from a preventive standpoint that will result in significant savings in adulthood from a healthcare perspective.

DEVELOPING GUIDELINES TO ESTABLISH THE STANDARD FOR QUALITY

Guidelines need to be developed based upon accepted recommendations, such as the Grades of Recommendation Assessment, Development and Evaluation system for rating the quality of the evidence and strength of evidence which is crucial for guideline development. Guidelines must adopt a high level of transparency in the development process. This is particularly relevant in the pediatric setting where there may be limited research using methods such as randomized controlled trials which would have a high level of rating from an evidence standpoint. As guidelines and policies related to quality need to be interpreted for specific settings, they should not be interpreted as standards of care.

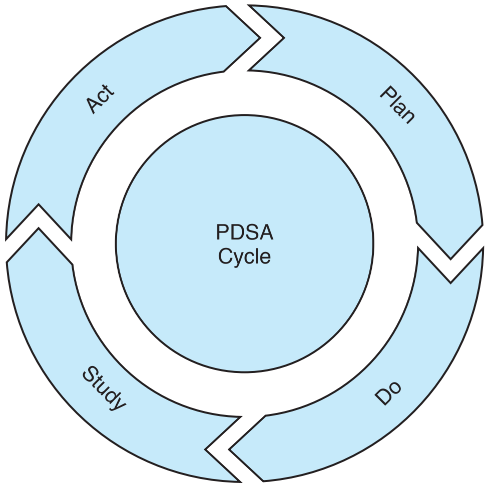

Figure 2-2 The plan-do-study-act cycle. *(From Langley GJ: The improvement guide: a practical guide to enhancing organizational performance, San Francisco, 1996, Jossey-Bass. © 1996 by Gerald J. Langley, Kevin M. Nolan, Thomas W. Nolan, L. Norman, and Lloyd P. Provost.)*

IMPROVING QUALITY

Achieving QI requires the adoption of a 3-step model: "Data → Information → Improvement." Quality needs to be measured. Quality data obtained from the measurement then needs to be converted into meaningful information that can be compared and reported. This quality measurement must also be actionable to achieve improvements in clinical practice. QI is a rapidly growing science. There are currently 4 techniques available for QI.

Model for Improvement

The *Model for Improvement* can be implemented using a framework of rapid cycle improvement also known as the *plan-do-study-act (PDSA) cycle* (Fig. 2-2). The PDSA cycle is typically aimed at testing small changes and then studying the results to plan and implement the next cycle of change (i.e., multiple PDSA cycles build on previous learning from PDSAs). Valuable information can be obtained from PDSA cycles that are successful, and those that are not, to help plan the next iteration of the PDSA cycle. The PDSA cycle specifically requires that improvements be data driven. This is important because many clinicians attempt to make changes for improvement in their practice but do not emphasize the importance of data collection.

The Model for Improvement has been successfully used in the **Vermont Oxford Network (VON)** to achieve improvements in care in

the **neonatal intensive care unit (NICU)** setting. The VON is a global network of collaborating NICUs involved in several studies that have favorably impacted the care of newborns. An example of a successful VON QI effort is a project aimed at reducing rates of chronic lung disease in extremely low birthweight infants. Clinical teams participating in this improvement effort used special reports from the VON database, reviewed the available evidence with content faculty experts, and then identified improvement goals. The teams received QI training through conference calls and emails for a period of 1 year. This effort resulted in a 37% increase in early surfactant administration for preterm infants achieving a high degree of QI.

Another example of a successful QI collaborative using the improvement model relates to the reduction of **catheter-associated bloodstream infections (CA-BSIs)** in the **pediatric intensive care unit (PICU)** setting. Similar to the VON experience, this effort included a group of PICUs that collaborated to impact a serious preventable problem in the PICU—*CA-BSIs*. National content experts and local PICU quality champions monitored and provided performance data at the local level in an almost real-time basis to ensure continued learning and improvement. The engagement of the entire PICU team—physicians, trainees, nurses, respiratory therapists, and others created a culture of quality and accountability. There was a strong emphasis on team learning across the participating institutions. This national collaborative sponsored by the Children's Hospital Association and the American Board of Pediatrics has resulted in a significant measurable reduction in CA-BSI rates across PICUs in the United States and is now in subsequent iterations of the PDSA cycle.

Six Sigma

Six Sigma relates to the reduction in *undesirable variation in processes* (Fig. 2-3). Every process has some level of inherent variation built into it. There are 2 types of variations in a process. *Random variation* relates to the variation that is inherent in the process simply because the process is being performed by humans. A physician completing a history and physical for a patient more than once may have a slightly different process each time, even though it is the same patient and the same physician. Random variation in processes is acceptable. In contrast, *special cause variation* relates to nonrandom variation that can adversely affect a process; when tracking infection rates in a nursery, a sudden increase in the infection rates may be secondary to poor handwashing techniques by a new healthcare provider in the system. This would represent a special cause variation (i.e., once this practice is improved, the infection rates will likely go back to the baseline level). Six Sigma attempts to provide a structured approach to unwanted variations in healthcare processes (Fig. 2-4). Six Sigma approaches have been successfully used in healthcare to improve processes in both the clinical and nonclinical settings.

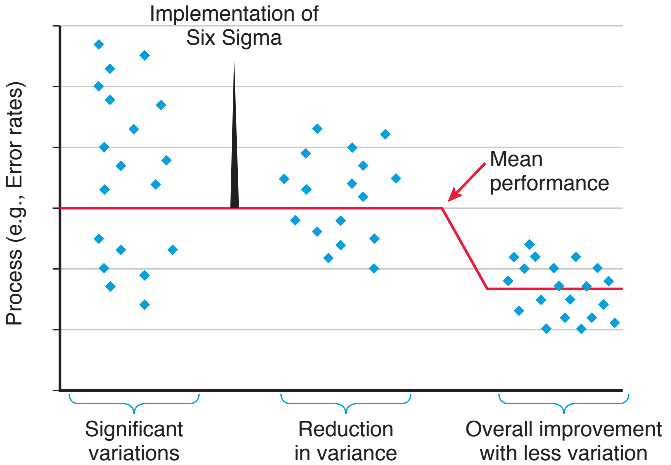

Figure 2-3 Improving quality by reducing variation and shifting the mean.

LEAN

Lean methodology, which stems from the Toyota Production System, aims at reducing waste within a process in a system. Figure 2-5*A* illustrates the steps in the process of a patient coming to the emergency department. After the initial registration, the patient is seen by a nurse and then the physician. In a busy emergency department, a patient may need to wait for hours before registration is complete and the patient is placed in the examination room. This wait time is a waste from the perspective of the patient and the family. By incorporating the registration process after placing the patient in the physician examination room, time can be saved and waste minimized (Fig. 2-5*B*). Lean

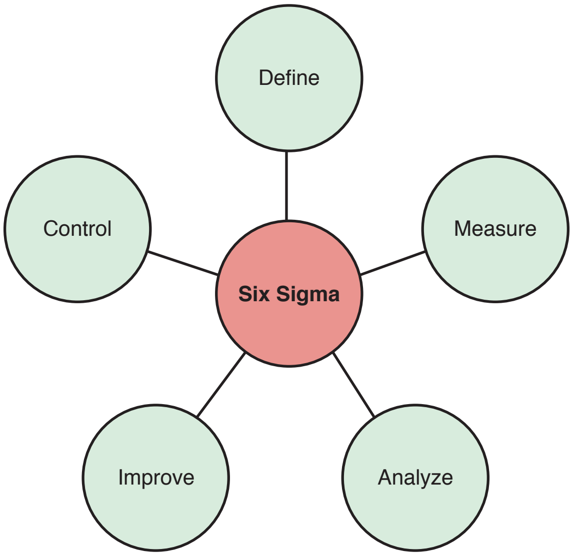

Figure 2-4 Six Sigma DMAIC (define, measure, analyze, improve, control) method.

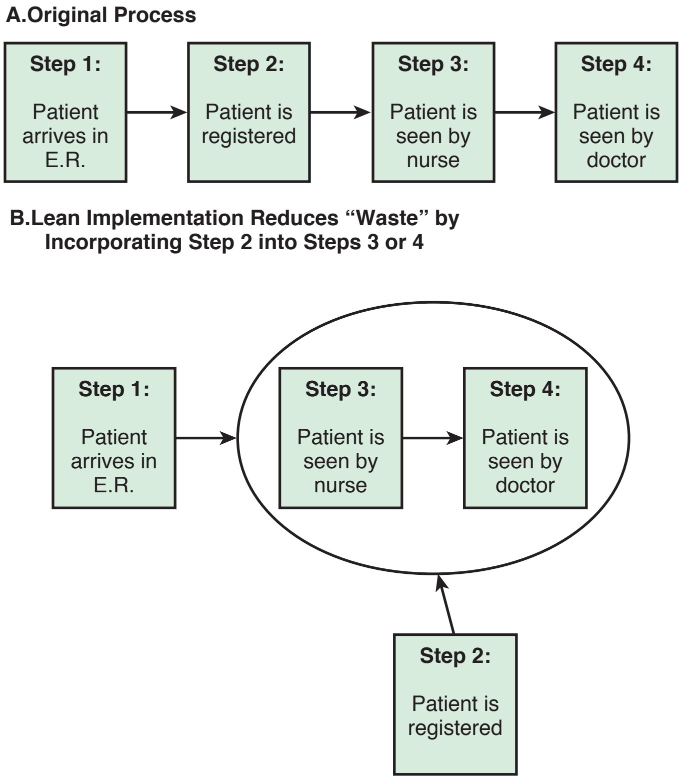

Figure 2-5 **A** and **B**, Lean—waste reduction.

methods have been successfully used in several outpatient and inpatient settings with resulting improvements in efficiency. Lean principles have also been adopted as a core strategy for children's hospitals with the goal of improving efficiencies and reducing waste.

Management Sciences

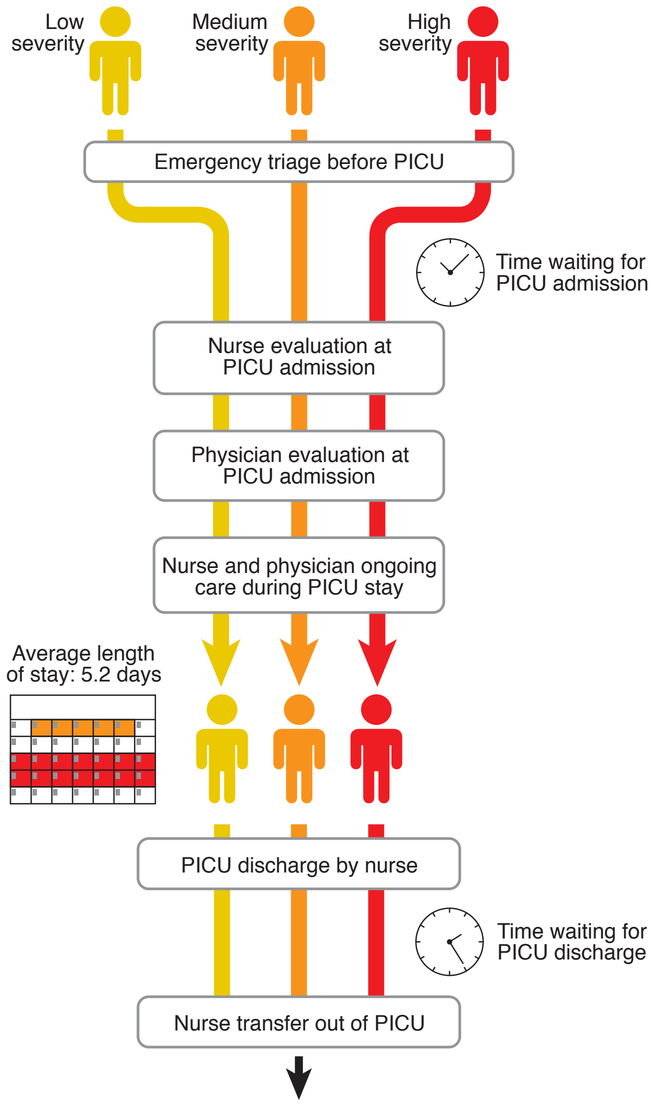
Management sciences, also known as *operations management*, stems from operations research and relates to the use of mathematical principles to maximize efficiencies within systems. Management sciences has been successfully used in many non–healthcare settings, such as airlines and the military. Management sciences principles have been successful in many European healthcare settings to optimize efficiencies in outpatient primary care office settings, inpatient acute care hospital settings, surgical settings including operating rooms, and also for effective planning of transport and hospital expansion policies. Management sciences principles are being explored for use in the U.S. healthcare system. One of the techniques for management sciences, *discrete event simulation* was used at the Children's Hospital of Wisconsin to effectively plan the expansion of the pediatric critical care services with the goal of improving quality and safety. The discrete event simulation model illustrated in Figure 2-6 depicts the various steps of the process in a PICU. Patients stratified across 3 levels of severity (low, medium, high) are admitted to the PICU, are initially seen by a nurse and physician, then stay in the PICU with ongoing care being provided by physicians and nurses, and are finally discharged from the PICU. The discrete event simulation model is a computer model developed using real estimates of numbers of patients, numbers of physicians and nurses in a PICU, and patient outcomes. Discrete event simulation models are created using real historical data, which allows testing the "what if" scenarios, such as the impact on patient flow and throughput by increasing the number of beds and/or changing nurse and physician staffing.

Another management sciences technique developed in Europe relates to the concept of *cognitive mapping*. Cognitive mapping aims at measuring the soft aspects of management sciences as illustrated in Figure 2-7. Cognitive mapping highlights the importance of perceptions and constructs of healthcare providers and how these constructs are linked in a hierarchical manner. Goals and aspirations of individual healthcare providers are identified by structured interviews and are mapped to strategic issues and problems, and options. By using specialized computer software, complex relationships can be identified to better understand the relationships between different constructs in a system. A discrete event simulation model views patient throughput based on numbers of beds, physicians, and nurses, and accounts for differences in patient mix. It does not account for many other factors, such as individual unit characteristics related to culture. By interviewing healthcare providers, cognitive maps can be developed that can help to better inform decision making.

DES Model

- Mathematically depicts a 24-bed PICU
- Depicts the patient experience from admission to discharge
- Factors the staffing of physicians and nurses in the PICU using historical experience
- DES Model starts with baseline and runs computer iterations to identify predicted outcomes with changing patient flow and staffing
- Results of DES Model provide insight into predicted outcomes of changing bed/staffing assumptions

Illustration of DES Model



Conclusions

- Simply adding new PICU beds will not improve patient flow in itself
- Critical ratio between MDs, RNs, and beds in PICU adjusted for patient severity is needed to maximize patient flow, safety, and outcomes

Figure 2-6 Management sciences—discrete event stimulation. PICU, pediatric intensive care unit.

MEASURING QUALITY

Robust quality indictors should have clinical and statistical relevance. Clinical relevance ensures that the indicators are meaningful in patient care from the standpoint of patients and clinicians. Statistical relevance ensures that the indicators have measurement properties to allow an acceptable level of accuracy and precision. These concepts are captured in the national recommendations that quality measures must meet the criteria of being valid, reliable, feasible, and usable (Table 2-2). Validity of quality measures relates to the notion that the measure is estimating the true concept of interest. Reliability relates to the notion that the measure is reproducible and provides the same result if retested. It is important that quality measures are feasible in practice. Quality measures must be useable, which means that they should be clinically meaningful. The **Agency for Healthcare Research and Quality** and the **National Quality Forum** have provided specific criteria to be considered when developing quality measures.

Quality indicators can be aimed at measuring the performance within 3 components of healthcare delivery: structure, process, and outcome (Fig. 2-8). Structure relates to the organizational characteristics in healthcare delivery. Examples of organizational characteristics are the number of physicians and nurses in an acute care setting and the availability and use of systems such as electronic health records. Process-related measures estimate how services are provided. Examples of a process measures are the percent of families of children with asthma who receive an asthma action plan as part of their office visit or the percent of hospitalized children who have documentation of

pain assessments as part of their care. Outcome measures relate to the final health status of the child. Examples of outcome measures are risk adjusted survival in an intensive care unit setting, birthweight-adjusted survival in the NICU setting, and functional status of children with chronic conditions such as cystic fibrosis.

It is important to distinguish between measures for accountability and measures for improvement. As illustrated in Figure 2-9, measures, particularly measures for accountability that may be linked to attribution and payment, must be based upon a rigorous process. This can be resource intensive and time-consuming. In contrast, measures for improvement serve a different purpose—to track incremental improvements linked to specific QI efforts. These may not undergo rigorous testing, but they have limited applicability beyond the specific QI setting.

Quality data can be quantitative and qualitative. Quantitative data includes numerical data, which can be continuous (patient satisfaction scores represented as a percentage with higher numbers indicating better satisfaction) or categorical (patient satisfaction scores obtained from a survey where a Likert scale is used indicating satisfactory, unsatisfactory, good, or superior care). Data can also be qualitative in nature, which includes nonnumeric data. Examples of qualitative data can include results from open-ended surveys related to the satisfaction of care in a clinic or hospital setting. It is important to be sensitive to the source and quality of data being obtained to ensure data quality.

Data measuring quality of care can be obtained from a variety of sources, which include chart reviews, patient surveys, existing administrative data sources (billing data from hospitals), disease and specialty databases, and patient registries, which track individual patients over time.

It is important to distinguish between *databases* and *data registries*. Databases are data repositories that can be as simple as a Microsoft Excel spreadsheet or as complex as relational databases using sophisticated servers and information technology platforms. Databases can provide a rich source of aggregated data for both quality measurement and research. Data registries allow tracking individual patients over time; this dynamic and longitudinal characteristic is important for population health management and QI.

Table 2-2 Properties of Robust Quality Measures

ATTRIBUTE	RELEVANCE
Validity	Indicator accurately captures the concept being measured.
Reliability	Measure is reproducible.
Feasibility	Data can be collected using paper or electronic records.
Usability	Measure is useful in clinical practice.

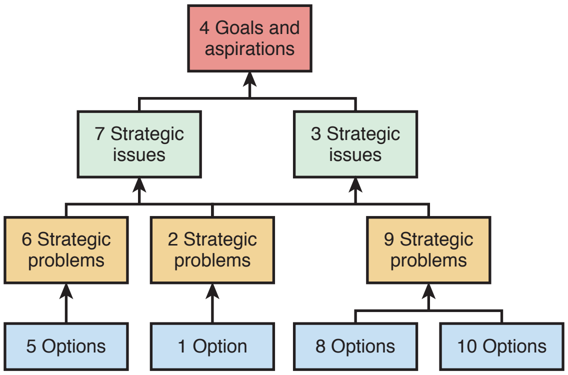


Figure 2-7 Management sciences—cognitive mapping.

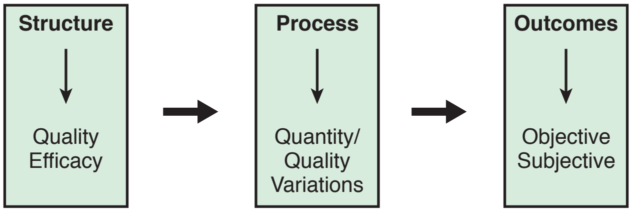

Figure 2-8 Donabedian model.

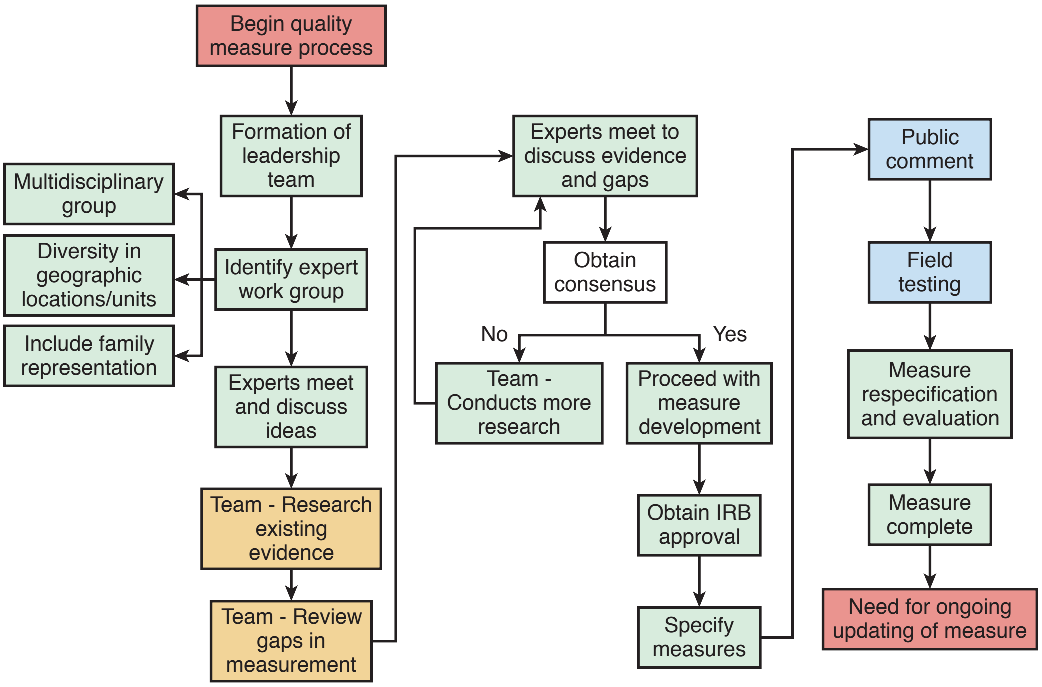

Figure 2-9 Development of a quality measure.

Data quality can become a significant impediment when using data from secondary sources, which can adversely impact the overall quality evaluation. Once data on the quality indicator has been collected, quality measurement can occur at 3 levels: (1) measuring quality status at 1 point in time (e.g., percent of children seen in a primary care office setting who received the recommended 2-year immunizations); (2) tracking performance over time (e.g., change in immunization rates in the primary care office setting for children 2 yr of age); and (3) comparing performance across clinical settings after accounting for epidemiologic confounders (e.g., immunization rates for children <2 yr of age in a primary care office setting stratified by race and socioeconomic status as compared to the rates of other practices in community and rates at national levels).

Pediatric quality measures are being developed nationally. Table 2-3 lists some of the important currently endorsed pediatric national quality indicators.

ANALYZING QUALITY DATA

Three approaches have been used for analyzing and reporting data. The classic approach from a research paradigm has been applied to quality data for statistically comparing trends over time, and differences before and after an intervention. P-values are interpreted as being significant if ≤0.05, which suggests that the likelihood of seeing a difference as extreme as observed has a probability of ≤5% (type I error). Another approach from an improvement science paradigm uses techniques such as run charts and control charts to identify special-cause variation. Special-cause variation attempts to capture observations that are unlikely to reflect random variation. Finally, quality data also has been reported on an individual patient level. This has gained popularity in the patient safety arena where identifying individual patient events in the form of descriptive analysis ("stories") may be more powerful in motivating a culture of change, rather than statistical reporting of aggregate data in the form of rates of adverse patient safety events.

COMPARING AND REPORTING QUALITY

There is an increasing emphasis on quality reporting in the United States. Many states have mandatory policies for the reporting of quality data. This reporting may be tied to reimbursement using the policy of P4P. P4P implies that reimbursements by insurers to hospitals and physicians will be partially based on the quality metrics. P4P can include both incentives and disincentives. Incentives relate to additional payments for meeting certain quality thresholds. Disincentives relate to withholding certain payments for not meeting those quality thresholds. An extension of the P4P concept relates to the implementation of the policy of **nonreimbursable hospital-acquired conditions**, formerly called "never events" by the **Centers for Medicare and Medicaid.** The Centers for Medicare and Medicaid has identified a list of hospital-acquired conditions, which are specific quality events that will result in no payment for care provided to patients (e.g., wrong site surgery, CA-BSI, and decubitus ulcers acquired in the hospital).

Quality reporting is also being used in a voluntary manner as a business growth strategy. Leading children's hospitals across the United States actively compete to have high ratings in national quality evaluations that are reported in publications such as *Parents* (formerly *Child)* magazine and *US News & World Report*. Many children's hospitals have also developed their own websites for voluntarily reporting their quality information for greater transparency. Although greater transparency may provide a competitive advantage to institutions, the underlying goal of transparency is to improve the quality of care being delivered, and for families to be able to make informed choices in selecting hospitals and physicians for their children.

Quality measures may also be used for purposes of certifying individual physicians as part of the MOC process. In the past, specialty and

Table 2-3 Examples of National Pediatric Quality Measures

NQF PEDIATRIC QUALITY INDICATORS	NQF-ENDORSED INPATIENT MEASURES AMONG PICUs	NQF-ENDORSED INPATIENT PEDIATRIC CARE MEASURES	NQF-ENDORSED OUTPATIENT PEDIATRIC CARE MEASURES

subspecialty certification in medicine, including pediatrics, was largely based on demonstrating a core fund of knowledge by being successful in an examination. No specific evidence of competency in actual practice needed to be demonstrated beyond successful completion of a training program. There continues to be significant variations in practice patterns even among physicians who are board certified, which highlights the concept that medical knowledge is important, but not sufficient for the delivery of high-quality care. Subsequently, the **American Board of Medical Specialties,** including its member board, the American Board of Pediatrics, implemented the MOC process in 2010. Within the MOC process, there is a specific requirement (Part IV of MOC) for the physician to demonstrate the assessment of quality of care and implementation of improvement strategies as part of recertification in pediatrics and subspecialties. Lifelong learning and the translation of learning into practice are the basis for the MOC process and for an essential competency for physicians professionalism. There are also discussions to adopt a similar requirement for Maintenance of Licensure for physicians by state medical regulatory boards.

The **Accreditation Council for Graduate Medical Education** requires residency programs to incorporate QI curriculum to ensure that systems-based practice and QI are part of the overall competencies within accredited graduate medical training programs. One form of **continuing medical education**, the **performance improvement** continuing medical education, is used for ongoing physician education. These initiatives require physicians to measure the quality of care they deliver to their patients, to compare their performance to peers or known benchmarks, and to work toward improving their care by leveraging QI methods. This forms a feedback loop for continued learning and improvement in practice.

Prior to comparing quality measures data both within and across clinical settings, it is important to perform risk adjustment to the extent that is feasible. **Risk adjustment** is the statistical concept that utilizes measures of underlying severity or risk so that the outcomes can be compared in a meaningful manner. The importance of risk adjustment was highlighted in the PICU setting many years ago. The unadjusted mortality rate for large tertiary care centers was significantly higher than that for smaller hospital settings. By performing severity of illness risk adjustment it was subsequently shown that the risks in tertiary care large PICUs were higher because patients had higher levels of severity of illness. These patients were sicker than other patients, which would explain the higher mortality rate. Although this concept is now intuitive for most clinicians, the use of severity of illness models in this study allowed a mathematical estimate of patient severity using physiologic and laboratory data, which allowed for the statistical adjustment of outcomes. This permits meaningful comparisons of the outcomes of large and small critical care units. Severity of illness models and the concepts of statistical risk adjustment are most developed in pediatric critical care, but these concepts are relevant for all comparisons of outcomes in the hospital settings where sicker patients may be transferred to the larger institutions for care and, therefore, would be expected to have poorer outcomes as compared to other settings with less sick patients.

Risk adjustment can be performed at 3 levels. First, patients who are sicker can be excluded from the analysis, thereby allowing the comparisons to be within homogenous groups. Although this approach is relatively simple to use, it is limited in that it would result in patient groups being excluded from the analysis. Second, risk stratification can be performed using measures of patient acuity. An example of this relates to the use of the **All-Patient Refined Diagnosis-Related Group** system where patients can be grouped or stratified into different severity criteria based on acuity weights. This approach may provide relatively homogenous strata within which comparisons can be performed, but it is not able to predict the overall outcomes within patient risk groups. Third, severity of illness risk adjustment relates to the use of clinical data to predict the outcomes of patient groups. An example of a clinical severity of illness risk adjustment process is the use of the **Pediatric Risk of Mortality (PRISM)** scoring system in the PICU setting. The PRISM score, and its subsequent iterations, composed of a combination of physiologic and laboratory perimeters that are weighted on a statistical logistic scale to predict the risk of mortality within that PICU stay. By comparing the observed and expected outcomes (i.e., mortality or survival), a quantitative estimate of the performance of that PICU can be established which can then be used to compare outcomes with other PICUs (standardized mortality ratio).

Risk-adjustment systems have been effectively incorporated into specialty databases. An example of such a system is the **Virtual Pediatric Intensive Care Unit System (VPS)**, which represents the pediatric critical care database system in the United States. The VPS, comprising more than 100 PICUs and cardiac PICUs across the United States, as well as international PICUs, currently has more than 300,000 patients within its database. The VPS database emphasizes data quality, both data validity and reliability, to ensure that the resulting data are accurate. Data validity has been established using standard data definitions with significant clinical input. Data reliability is established using interrater reliability to ensure that the manual data collection that involves several data collectors within pediatric institutions is consistent. The PRISM scoring system is programmed into the VPS software to allow the rapid estimation of the severity of illness of individual patients. This, in turn, allows risk adjustment of the various outcomes that are compared within institutions over time and across institutions for purposes of QI.

QUALITY AND PATIENT SAFETY

Safety is an important dimension of quality, and errors in healthcare are a leading cause of death and injury. Approximately 3-4% of hospitalized adult patients are harmed by the care that is supposed to help them, and 7% are exposed to a serious medication error that harms or could harm them. Multiple factors contribute to errors: an increasingly complex healthcare system with diffuse accountability; a culture of attributing errors to individuals, which overlooks problematic systems; lack of allegiance between physicians and hospitals, which detracts from patient-centered practices; and reimbursement policies that frequently discourage safety measures.

Medical Errors in Children's Healthcare

Few epidemiologic data are available regarding medication errors in the pediatric setting, and the *potential* for pediatric inpatient medical errors is substantial. This may be partly a result of children having unique clinical experiences that are prone to error. These unique risk factors or safety issues, the "4 Ds," are **developmental change, dependence on adults, different disease epidemiology,** and **demographic characteristics.** *Developmental change* might refer to the unique susceptibility of neonates to infections or the need for weight-based dosing with growth. Children's *dependence on adults* puts them at heightened risk for experiencing medical errors because children do not usually manage their own treatments or provide their own medical history and may not have the insight to question their own care. *Different disease epidemiology* refers to the unique illnesses and medical needs that predispose children to unique safety events as compared with adults (e.g., birth trauma and screening for metabolic abnormalities). Children have distinct *demographic characteristics* and are more likely to live in poverty than any other segment of the population.

Adverse drug events (ADEs) may occur in pediatric patients at a similar rate as in adult patients; the potential ADE rate may be 3 times higher in children. A *potential* ADE is one that is intercepted before causing harm. Most potential ADEs occur at the stage of drug ordering and involve incorrect dosing, antiinfective drugs, and intravenous medications. In an ambulatory setting, 13% of prescriptions for children had potential medication errors. These errors are more common for infants and toddlers, children obtaining multiple prescriptions at the same time, and prescriptions for analgesics/narcotics. Technology software does not always address issues specific to children, such as pediatric dosing calculations and age-based normal ranges. It is estimated that inpatient nonmedication errors involving children result in more than $1 billion in reconciliation costs per year and are associated with significant increases in length of stay, charges, and in-hospital deaths.

Key Issues in Patient Safety

Making care safer requires the identification and control of things that could cause harm to patients. Several key concepts regarding patient safety are summarized in the following sections and are available in curriculum overviews at www.patientsafety.gov, www.npsf.org, and www.va.gov.

Systems Approach

The majority of healthcare errors result from faults intrinsic to the processes by which healthcare is delivered, rather than individual mistakes. This systems approach compels organizations to respond to adverse events not by blaming individuals, but by improving the conditions under which individuals work. An error is viewed as a symptom of trouble in a process that offers an opportunity for improvement and the potential to implement safeguards.

Developing a Culture of Safety

The biggest challenge in making the health system safer is changing the culture from one of treating errors as personal failures to one of treating errors as opportunities to improve the system. Organizations need to foster a culture of learning in which each individual will feel accountable for ensuring a safe and quality program, communication is open, and teamwork is valued. Reporting of errors should be valued, reports of adverse events should be handled confidentially, and those who report errors should be protected from discovery. Developing a culture of learning involves the compassionate and appropriate disclosure of system failures and medical errors to patients and families. It has also been shown that utilizing multiple approaches to identify adverse events may be effective.

Communication. Good communication among the healthcare team is essential for patient safety. Healthcare involves the safe transfer of responsibility for patient care and the transfer of patient information. Poor communication or miscommunication creates the opportunity for incorrect or incomplete transfer of vital information during the transfer of responsibility for patient care from one provider to another, thus placing the patient at risk for serious medical error. The potential for harm is increased when the healthcare team and the patient do not share a native language. Errors in medical interpretation are common, with omissions being the most frequent. Ad hoc interpreters are significantly more likely to commit errors with harmful clinical consequences than are hospital interpreters.

Teamwork and Authority Gradients. Ensuring a systems approach to healthcare safety involves a paradigm shift. Healthcare has tended to be a hierarchical endeavor, with physicians in leadership roles that allowed significant amounts of autonomy. This authority gradient can predispose to communication failures: junior team members may be hesitant to speak up and senior members may resist feedback. A medical student or nursing assistant may be hesitant to inform an attending physician of a potential error. In a culture of safety, team members with different positions of authority must interact to facilitate optimal patient care; all are empowered to voice a safety concern. The composition of the teams may vary day to day because of shifting schedules. Senior leaders must be able to engender trust rapidly among team members, accept that human error is inevitable, and encourage behaviors that prevent or mitigate the harm that results from errors. Healthcare can learn important lessons for safety from industry. Experiences from industries that have standardized and achieved a high level of safety and reliability (e.g., the airline and nuclear industries) can help inform future healthcare systems in both developing and industrialized nations.

Human Factors Engineering. **Human factors engineering (HFE)** is a discipline concerned with the design of tools, machines, and systems that take into account human capabilities, limitations, and characteristics. It builds on ergonomics and utilizes what is known about human performance and system interaction. HFE can play an important role in the optimal design of equipment, the development of effective processes, monitoring for unintended consequences, and the planning for and introduction of new technologies. HFE techniques used to identify hazards or areas for improving safety can be proactive (addressing complex areas of healthcare before implementing an intervention) or reactive (reviewing reports of "close calls" or injuries). Computerized physician order entry, an example of HFE in healthcare, has been shown to decrease the rate of medication errors in pediatric inpatient settings.

The role of a team based approach along with the need to consider human factors requires the creation of systems that are designed to improve outcomes. Recent studies from the nursing literature has identified the positive impact of continuity of nursing care on patient outcomes in high-risk settings, and also the potential detrimental impact on patient outcomes with unduly long nursing shifts in the inpatient acute care setting for children.

Reliability. Reliability in healthcare is defined as the measurable capability of a process, procedure, or health service to perform its intended function in the required time under commonly occurring conditions (i.e., providing intended care on a consistent basis). Most healthcare organizations currently perform at *Level 1 reliability*, which means that processes are performed with only an 80-90% success rate. To achieve *Level 2 performance* (≤5 failures/100 opportunities), processes must be *intentionally designed* with tools and concepts based on the principles of HFE. Performance at *Level 3* (≤5 failures/1,000 opportunities), requires a well-designed system with low variation and cooperative relationships and a state of what has been called "mindfulness," where attention is paid to processes, structure, and their relationship to outcomes. Cincinnati Children's Hospital Medical Center used reliability science and the Model for Improvement to institute a ventilator-associated pneumonia protocol that led to an 87% reduction in ventilator-associated pneumonias per 1,000 ventilator days (from a fiscal year average of 7.5 to an average of only 0.95).

Such efforts are now expanding from individual institutions to the regional level. The Solutions for Patient Safety is a new collaboration of multiple pediatric institutions at a state level to share quality and safety data in a transparent manner, and to create a culture of shared learning.

IMPLICATIONS OF THE U.S. HEALTHCARE REFORM FOR QUALITY

In 2010, the Affordable Care Act was enacted into law. This significant health care legislation attempting to achieve the vision of universal health care includes an emphasis on access to health care, the implementation of consumer protections (e.g., preexisting conditions), and improving quality and lowering the cost of health care.

Regarding quality and safety in health care for children, health care reform has three key implications. First, universal coverage optimizes access and includes expanding coverage for young adults to age 26 yr. Second, various initiatives related to quality, safety, patient-centered outcomes research, and innovation were implemented and funded. For example, the Agency for Healthcare Research and Quality (AHRQ) has funded a national effort to establish seven centers of excellence through the Pediatric Quality Measurement Program (PQMP) to improve existing pediatric quality measures and create new measures that can be used by states and in a variety of other settings to evaluate quality of care for children. Third, a paradigm shift in the existing model of health care delivery system has been vertically integrated toward a model of horizontal integration. This has led to the creation and rapid growth of integrated delivery systems and risk-sharing relationships of accountable care organizations (ACOs).

Accomplishing this strategic direction is resulting in three new areas of rapid growth in the quality arena. "Big Data" relates to the notion of linking potentially disparate sources of data to generate new knowledge, accelerate innovation, and improve outcomes. Big Data is unique in that it aims to link structured and unstructured data sources, including data emerging from databases, registries, clinical records, and social media. A key strength of using a large volume of data across multiple sources by linking it to create Big Data is a significant increase in power for early prediction and new knowledge generation that can be rapidly implemented.

Another area of increasing emphasis is the notion of population health. This is important because it expands the traditional role of

physicians to improve quality of care for individual patients to also improve the quality of care for larger populations. Populations can be defined by geographic constraints or disease/patient condition. The notion of population health is integral for achieving the “triple aim” vision of quality of care. Efforts to link payment and reimbursement for care delivery by physicians and health systems are being increasingly tied to measurable improvements in population health. To achieve a meaningful improvement in population outcome, physician practices will need to embrace the emerging paradigm of practice transformation. Practice transformation has many facets, including the adoption of a “medical home,” the seamless connectivity across the primary care and subspecialty continuum, and a strong connection between the medical and social determinants of health care delivery. To implement successful practice transformation, hospitals are increasingly adopting a broader view to evolve into health care systems that serve children across the entire range of the care continuum, including preventive and primary care, acute hospital care, and partnerships with community organizations for enhancing the social support structure. In addition, new risk-sharing payment models are evolving, resulting in the growth of entities such as ACOs, which represent a financial risk-sharing model across primary and subspecialty care and hospitals, resulting in an unprecedented level of health care integration to improve quality of care.

THE EVOLUTION OF QUALITY TO OUTCOMES TO VALUE

Most efforts at QI tend to emphasize enhancements in the process of healthcare delivery with the assumption that this will lead to improvements in outcomes. With the growing adoption of electronic health records that can allow tracking patients across the continuum of care, it will be possible to measure outcomes. Efforts at quality and outcomes must move toward creating value from the perspective of patients and families. Healthcare delivery systems must be developed based upon patient needs. Healthcare providers should lead this initiative to create value and that outcomes being measured should matter to patients.

INFORMATION TECHNOLOGY AND QUALITY IMPROVEMENT

The underlying goal of the HIT movement is to improve quality and safety. HIT includes electronic health records, personal health records, and health information exchange. The purpose of a well-functioning electronic health record is to allow collection and storage of patient data in an electronic form, to allow this information to be provided to clinicians and healthcare providers, to have the ability to allow clinicians to enter patient care orders through the **computerized physician order entry,** and to have the infrastructure to provide clinical decision support which will improve physician decision making at the level of individual patients. Personal health records will allow patients and families to be more actively engaged in managing their own health by monitoring their clinical progress and laboratory information, and also be able to communicate with their physicians for appointments, obtaining medications, and getting their questions answered. Appropriate, timely, and seamless sharing of patient information across physician networks and healthcare organizations is critical to quality care and to achieve the full vision of a *medical home* for children. Health information exchange would allow the sharing of healthcare information in an electronic format to facilitate the appropriate connections between providers and healthcare organizations within a community or region. However, significant cost and time barriers remain for adoption of HIT. The entire field of HIT as a mechanism to improve quality is likely to continue to be in the forefront of the quality journey for physicians and healthcare organizations for the next several years.

Despite the emphasis on HIT and data, it is important to understand that data does not lead to improvement in itself. Improvement is an affirmative choice and requires translating data (measurement) into clinically relevant information (data that has context and relevance) that is actionable for QI.

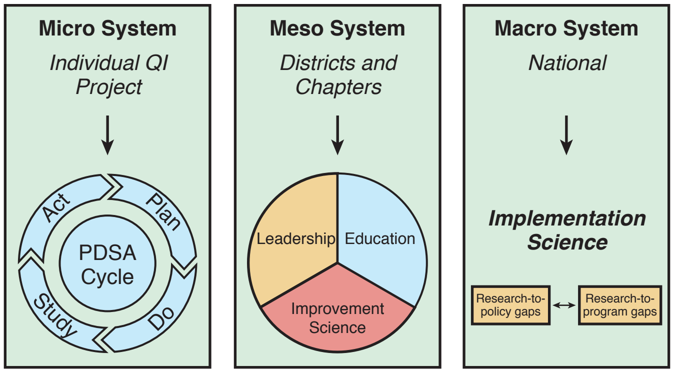

Figure 2-10 Success ingredients for large-scale quality improvement.

QUALITY IMPROVEMENT OR RESEARCH?

Research aims at generating new knowledge. QI aims at implementing the new knowledge into practice. Whereas research aims at developing new generalizable knowledge, QI aims at adopting the available evidence into practice at a local level. With the growing interest of research in the field of QI and efforts to expand the generalizability of QI initiatives, there can be situations in which research and QI overlap. In the future, the gap between QI and research will likely narrow to allow a continuum of active knowledge transfer from research into practice using QI methods.

EXPANDING INDIVIDUAL QUALITY IMPROVEMENT INITIATIVES TO SCALE

Despite the success of individual QI and patient safety projects, the overall progress to achieve large-scale improvements to reach all children across the spectrum of geographic location and socioeconomic status remains limited. This contributes to the health disparities that persist for children with significant differences in access and quality of care. A potential factor that limits the full impact of QI is the lack of strategic alignment of improvement efforts with hospitals, health systems, and across states.

This challenge can be viewed from a system standpoint in being able to conduct and expand QI from a micro level (individual projects), to the meso level (regional), to the macro level (national and international). The learning from individual QI projects for addressing specific challenges can be expanded to the regional level by ensuring that there is optimal leadership, opportunity for education, and adoption of improvement science (Fig. 2-10). To further expand the learning to a national and international level, it is important to leverage implementation science to allow a strategic approach to identification of the key success ingredients to expand the improvement strategy. To fully leverage the synergies to impact the quality of care delivered to children, it is important for national and international healthcare organizations to effectively collaborate from a knowledge management and improvement standpoint (Table 2-4).

INTERNATIONAL EFFORTS FOR QUALITY IMPROVEMENT

The implications of QI for healthcare delivery systems are equally relevant to international venues as to the United States. Many developing and industrialized countries are in the process of expanding their pediatric care delivery systems to have a greater presence of tertiary and quaternary care delivery. The understanding and adoption of QI principles during the early phase of expansion will result in the efficient use of resources with the greatest potential for favorably impacting health outcomes in children. Pediatric clinical practices in many developing countries have already adopted several unique, innovative approaches to allow delivery and creation of healthcare systems despite limited resources. These local innovations need to be expanded to allow for learning across countries. QI provides a unique strategy that can result in linking of a global community for the care of children including real-time learning and sharing of innovative best practices

Table 2-4 National Organizations Involved in Pediatric Quality Improvement

ORGANIZATION	ROLE	ACTIVITIES
American Academy of Pediatrics (AAP)	Represents more than 60,000 pediatricians and pediatric subspecialists worldwide	Resources for QI to improve health for all children, best practices, advocacy, policy, research and practice, and medical home
American Board of Pediatrics (ABP)	Certifying board for pediatrics and pediatric subspecialties	Certification policies and resources for activities such as Maintenance of Certification (MOC)
American Medical Association (AMA)	Physician member association	Physician Consortium for Performance Improvement (PCPI)—physician-led initiative
Children's Hospital Association (CHA)	Formerly the National Association of Children's Hospitals and Related Institutions; and the Child Health Corporation of America	Databases, QI collaboratives, and policy
Institute for Healthcare Improvement (IHI)	QI organization for adult and pediatric care	QI collaboratives, QI educational workshops and materials
National Initiative for Child Health Quality (NICHQ)	QI organization for pediatric care	QI training, improvement networks
Joint Commission	Hospital accreditation organization	Unannounced surveys to evaluate quality of care in hospitals
National Committee for Quality Assurance (NCQA)	QI organization	Healthcare Effectiveness Data and Information Set (HEDIS) and quality measures for improvement
National Quality Forum (NQF)	Multidisciplinary group including healthcare providers, purchases, consumers, and accrediting bodies	Endorsing national quality measures, convening expert groups, and setting national priorities

across the developing and industrialized worlds. Many international efforts to improve QI are already in progress. For example, the World Health Organization (WHO) has highlighted the global progress in adoption of HIT in many countries. A survey performed by WHO between 2005 and 2006 identified that nearly half of 112 countries responding to the survey already have national task forces or related groups to provide the national direction for e-health strategies. Pediatricians have the unique opportunity to provide leadership to evolving governmental-private-public partnerships in designing the next generation of pediatric healthcare delivery systems.

Chapter 3

Ethics in Pediatric Care

Eric Kodish and Kathryn L. Weise

Pediatric ethics is the branch of bioethics that analyzes moral aspects of decisions made relating to the healthcare of children. In general terms, the **autonomy**-driven framework of adult medical ethics is replaced by a **beneficent** paternalism (or parentalism) in pediatrics. Pediatric ethics is distinctive because the pediatric clinician has an independent fiduciary obligation to act in a younger child's **best interest** that takes moral precedence over the wishes of the child's parent(s). For older children, the concept of **assent** suggests that the voice of the patient must be heard. These factors create the possibility of conflict among child, parent, and clinician. The approach to the ethical issues that arise in pediatric practice ***must*** include respect for parental responsibility and authority balanced with a child's developing capacity and autonomy. Heterogeneity of social, cultural, and religious views about the role of children adds complexity.

ASSENT AND PARENTAL PERMISSION

The doctrine of informed consent has limited direct application to children and adolescents who lack decisional capacity. The capacity for informed decision making in healthcare involves the ability to understand and communicate, to reason and deliberate, and to analyze conflicting elements of a decision using a set of personal values. The age at which a competent patient may legally exercise voluntary and informed consent for medical care varies from state to state and may be limited to specific conditions (sexually transmitted infections, family planning, drug or alcohol abuse).

In contrast to decisions about one's own care, a parent's right to direct a child's medical care is more limited. For this reason, the term *parental consent* is misleading. The concept of parental permission (rather than consent) reflects a *surrogate* or *proxy* decision made by a parent on behalf of a child. It is constrained both by the child's best interest and the independent obligation of clinicians to act in the child's best interest, even if this places them in conflict with a parent. In any given instance, the decision of what is or is not in a child's best interest may be difficult, especially given the diverse views of acceptable child rearing and child welfare. Parents are (and should be) granted wide discretion in raising their children. In cases involving a substantial risk of harm, the moral focus should be on avoiding or preventing harm to the child, not on a parental right to decide. While the term "best" interests may be too high of a threshold requirement, a minimum standard of "basic" interests is ethically obligatory.

Respect for children must account for both a child's vulnerability and developing capacity. This respect encompasses both the protective role of parental permission and the developmental role of **child assent** (the child's affirmative agreement). Understanding the concept of assent is one of the major conceptual challenges in pediatric ethics. The dissent (or disagreement) of a child is the opposite of assent and is also morally relevant. Pediatric ethics ***requires*** clinicians and parents to override a child's dissent when a proposed intervention is essential to the child's welfare. Otherwise, assent should be solicited and dissent should be honored. In seeking younger children's assent, a clinician should help them understand their condition, tell them what they can expect, assess their understanding and whether they feel pressured to assent, and solicit their willingness to participate. All efforts must be made to delineate situations in which the test or procedure will be done regardless of the child's assent/dissent, and in such cases the charade

of soliciting assent should be avoided. There is an important distinction between soliciting assent and respectfully informing a child that a test or procedure will take place regardless of the child's decision. Optimally, an educational process can transpire (if time allows) to gain the trust and assent of the child-patient. When this cannot occur, pediatric ethics requires that clinicians apologize to a child for acting to override dissent.

Older children or adolescents may have the cognitive and emotional capacity to fully participate in healthcare decisions. If so, the adolescent should be provided with the same information as would be given to an adult patient. In cases like this, the patient may be able to provide informed consent ethically but not legally. The adolescent's parent(s) remain in a guiding and protective role. The process of communication and negotiation will be more complex should disagreement arise between the parent and adolescent.

TREATMENT OF CRITICALLY ILL CHILDREN

Infants, children, and adolescents who become critically ill may recover fully, may die, or may survive with new or worsened limitations of function. Uncertainty about outcomes can make planning goals of care difficult, or if misunderstandings between patient, families, and medical staff occur, may drive conflict over treatment proposals. Ethical issues that arise during critical illness include balancing benefits, burdens, and harms of therapy in the face of uncertainty; maintaining a helpful degree of transparency and communication about medical standards of care at an institution; understanding and respecting religious and cultural differences that impact requests for or refusal of treatments; defining limits of therapy based on assessments of medical futility; recognizing the moral equivalence of not starting an ineffective treatment and stopping (although the 2 acts may feel very different to families and providers); and controversies such as withholding medically administered nutrition and hydration.

Transitioning the Goals of Care

Most acutely ill children who die in an ICU do so after a decision has been made to either forgo or withdraw **life-sustaining medical treatment (LSMT)**, and the same may apply in the chronically ill population. LSMT is justified when the anticipated benefit outweighs the burdens to the patient; the availability of technology does not in and of itself obligate its use. Decisions to use, limit, or withdraw LSMT should be made after careful consideration of all pertinent factors recognizable by both family and medical staff, including medical likelihood of particular outcomes, burdens on the patient and family, religious and cultural decision-making frameworks, and input by the patient when possible. Although fear of legal repercussions may sometimes drive treatment and medical advice, ultimate decisions should be based on what is thought to be best for the patient rather than based on fears of litigation.

The concept of **futility** has been used to support unilateral forgoing of LSMT against the wishes of patients and families by holding that clinicians should not provide futile (or useless) interventions. If medical futility is defined narrowly as the impossibility of achieving a desired physiologic outcome, then forgoing a particular intervention is ethically justified. However, this approach may not adequately engage professionals and families in understanding facts and values that might allow the same therapy to reach other goals, and may leave medical and family stakeholders in permanent conflict. If agreement cannot be reached through clear and compassionate communication efforts, further input can be sought from an ethics consultant or committee.

Communication about life-threatening or life-altering illness is challenging, and requires skills learned through both modeling and practice. These skills include choosing a setting conducive to what may become 1 or more long conversations; listening carefully to children's and families' hopes, fears, understanding, and expectations; explaining medical information and uncertainties simply and clearly without complicated terms and concepts; conveying concern and openness to discussion; and being willing to share the burdens of decision-making with families by giving clear recommendations. Discussing difficult topics with children requires an understanding of child development, and can be aided by professionals such as child psychologists or child life specialists. Such conversations and their outcomes have a major impact on the future care of the patient, on families, and on medical staff. For this reason, ongoing evaluation of goals and communication about them is needed with families and within complex medical teams as the course of the illness unfolds.

Experts recognize that good medical care involves providing for communication, symptom management, and a range of supportive services from the onset of acute illness. In this way, if an illness proves to be life-limiting in spite of aggressive therapies, the elements of palliative care are already in place. This concept has had difficulty gaining traction, especially in critical care settings, because of the mistaken conflation of broadly defined palliative measures with hospice care. Palliative care interventions focus on the relief of symptoms and conditions that may detract from quality of life regardless of the impact on a child's underlying disease process, and as such are important whether care is focused on cure or on transitioning to end-of-life care (see Chapter 43). Some interventions regarded as life-sustaining, such as chemotherapy, may be ethically acceptable in the end-of-life setting if their use decreases pain and suffering rather than results only in prolonging death.

Withholding and Withdrawing Life-Sustaining Treatment

Limitation of interventions or withdrawal of existing therapies are ethically acceptable if they are congruent with a plan of care focused on comfort and improved quality at the end of life rather than cure. The prevailing view in Western, traditional medical ethics is that there is no moral distinction between withholding or withdrawing interventions that are not medically indicated. Uncertainty in predicting a child's response to treatment may drive the initiation and continuation of interventions that are no longer supportive of shared goals of care. It is necessary to continually evaluate the results of these treatments and the evolution of the illness to recognize whether such interventions continue to be the best medical and moral choices. Maintaining the focus on the child rather than on the interests of parents or medical staff will help guide decision making.

The decision about whether or not to attempt **cardiopulmonary resuscitation** may become an issue to discuss with parents of children living with life-threatening or terminal conditions. All elements of end-of-life care approaches, including resuscitation status, should be supportive of agreed-on goals of care. It is imperative that decisions and plans are effectively communicated to all caregivers in order to avoid denying medically effective interventions and measures to ensure comfort. Orders about resuscitation status should clarify the plan regarding intubation and mechanical ventilation, the use of cardiac medications, chest compressions, and cardioversion. Because goals of care may change over time, a medical order regarding resuscitation is not irrevocable. Clinicians may assume that the absence of a do-not-attempt-resuscitation (DNAR) order obligates them to perform a prolonged resuscitation. This action may not be ethically supportable if resuscitative efforts will not achieve the desired physiologic endpoint. In all cases, treatments should be tailored to the child's clinical condition, balancing benefits and burdens to the patient. Resuscitation should not be performed solely to mollify parental distress at the tragic time of the loss of their child.

Advance Directives. An advance directive (AD) is a mechanism that allows patients and/or appropriate surrogates to designate the desired medical interventions under applicable circumstances. Discussion and clarification of resuscitation status should be included in advance care planning, and for children attending school in spite of advanced illness, may need to be addressed in that setting. Decisions regarding resuscitation status in the out-of-hospital setting can be an important component of providing comprehensive care.

The 1991 federal Patient Self-Determination Act requires that healthcare institutions ask adult (>18 yr) patients whether they have completed an AD and, if not, inform them of their right to do so. Few states support creation of broad ADs for minors because ADs are

traditionally created by persons with legal decision-making capacity, but some have moved in this direction because it is recognized that minors may be capable of participating in decision making, especially if they have been dealing with chronic disease. However, surrogate decision makers may participate in advance care planning for their children. Most states have approved the implementation of prehospital or portable DNAR orders, through which adults may indicate their desire not to be resuscitated by emergency personnel. On a state-by-state basis, portable orders regarding resuscitation status may also apply to children. If DNAR orders exist for an infant or a child, it is important to communicate effectively about their intent among all potential caregivers, because nonmedical stakeholders such as teachers or sitters may not wish to be in the position of interpreting or honoring them. Some institutions have established local policies and procedures by which an appropriately executed outpatient DNAR order can be honored upon a child's arrival in the emergency department. Key features may include a standardized document format, review by an attending physician, ongoing education, and involvement of a pediatric palliative medicine service.

In cases involving prenatal diagnosis of a lethal or significantly burdensome anomaly, parents may choose to carry their fetus/unborn child to term in order to cherish a short time with the infant after birth, but do not feel that resuscitation or certain other aggressive measures would support their well-considered goals of care. In this setting, a birth plan explaining the reasons for each choice can be developed by the parents and medical staff prior to delivery and shared with involved medical staff. This approach gives staff a chance to find other caregivers if they are uncomfortable with the approach, without abandoning the care of the child. If, after evaluation at birth, the infant's condition is as had been expected, honoring the requested plan is ethically supportable and should be done in a way that optimizes comfort of the infant and family.

Many states utilize **Physician Orders for Life-Sustaining Treatment** or **Medical Orders for Life-Sustaining Treatment** approaches to communicating a patient or surrogates wishes regarding advance care planning. It is important for pediatricians to learn which pathways for communicating goals of care are available in their own states.

Artificial Hydration and Nutrition. Issues surrounding withholding or withdrawing artificial hydration and nutrition are controversial, and interpretations are affected by parental, religious, and medical beliefs. Any adult or child who is fully dependent on the care of others will die as a result of not receiving hydration and nutrition. Case law has supported the withholding of artificially administered nutrition and hydration in the setting of adult vegetative or permanently unconscious patients who can be shown to have previously expressed a wish not to be maintained in such a state. This requires a valid AD, or for a surrogate decision maker to speak on behalf of the patient's known wishes. Because infants and many children have not reached a developmental stage in which such discussions would have been possible, decisions about stopping artificially administered nutrition and hydration as a limitation of treatment are more problematic. These decisions should be based on what families and caregivers decide best support comfort. In the child who is imminently dying, unaware of hunger, does not tolerate enteral feedings, and in whom family and staff agree that IV nutrition and hydration only prolong the dying process, it may be ethically supportable to withhold or withdraw these treatments based on a benefit–burden analysis.

The Doctrine of Double Effect. Treatment decisions at the end of life may include limitations of certain LSMT, or may involve the use of analgesic or sedative medications that some fear may shorten life, thereby causing death. The doctrine of double effect holds that an action with both good and bad effects is morally justifiable if the good effect is the only one intended, and the bad effect is foreseen and accepted, but not desired. In pediatrics, it is most commonly applied in end-of-life cases, when upward titration of medication (opiates) necessary to relieve pain, anxiety, or air hunger can be expected to result in a degree of respiratory depression. In such cases, meeting a provider's obligation to relieve suffering is the intended effect, and this obligation to the patient outweighs the acknowledged but unavoidable side effect. Choosing medications that adequately relieve symptoms with minimal adverse effects would be ethically preferable, but the obligation to provide comfort at the end of life outweighs the foreseeable occurrence of unavoidable side effects. Hastening death as a primary intention is not considered to be morally acceptable.

Providing pain medication guided by the doctrine of double effect should not be confused with active euthanasia. The distinction is clear:

- In active euthanasia, causing death is chosen as a means of relieving the symptoms that cause suffering.
- Under the doctrine of double effect, adequate management of pain, anxiety, or air hunger is recognized as an obligation to dying patients, and is provided by careful titration of medications in response to symptoms. If death occurs sooner as a result, this is accepted.

In both cases the patient dies and in both cases suffering ends, but immediate death is the intended consequence only in the case of euthanasia. Codes of ethics and legislation in many states support the obligation to provide pain and symptom relief at the end of life, even if this requires increasing doses of medication.

CARE OF DISABLED NEWBORNS

In 1982, an infant with Down syndrome and esophageal atresia was allowed to die at 6 days of age at the parents' request. Prior to this case becoming public, prevailing opinion was that withholding aggressive treatments from infants who were predicted to be significantly disabled from conditions such as Down syndrome or meningomyelocele was ethically acceptable, and was being done on advice of physicians who felt that they and families should be able to decide what was best for an individual infant. The public legal controversy resulted in federal legislation called the "Baby Doe Regulations," prohibiting the withholding of medically beneficial treatment from disabled infants except under conditions of permanent unconsciousness, "futile" treatment, and "virtually futile" treatment that imposes excessive burdens on the infant. Today, treatment options and potential outcomes have improved, attitudes toward and social supports for disabled children have evolved, and initial aggressive treatment of infants with severe disabilities has become more common. Studies done since the Baby Doe Regulations went into effect indicate that most pediatricians supported parental rather than government control of such decisions, and felt that they were now constrained to institute treatments that served neither patients nor families well.

One consequence of the legislation was a shift from potential undertreatment to widespread overtreatment (LSMT that does not serve the interests of the child) of severely disabled newborns. The legislation has been difficult to enforce, and subsequent case law has upheld the right of a parent to decide to forgo LSMT in certain instances. The 2002 "Born Alive Act" defined a human being as any infant born alive at any stage of development. It has been thought by some to pose a risk to the ethical practice of providing palliative care for newborns, though many believe that no changes in patient management are necessary.

Active euthanasia of severely suffering disabled newborns has been legalized in the Netherlands, using a protocol designed to minimize risk of abuse and maximize transparency. Although there may be some controversy over the subject in the United States, there is consensus that active euthanasia is not ethically acceptable in the care of infants and children.

DECLARING DEATH AND ORGAN DONATION

Donation of solid organs necessary to support life can occur after a patient is declared dead based on either irreversible cessation of neurologic function of the brain and brainstem (death by neurologic criteria, or "brain death") or a predetermined period of cardiac asystole called "circulatory death." To avoid a potential conflict of interest by surgeons or others caring for a potential organ recipient, the request for organ donation should be separated from the clinical discussion of either brain death or withdrawal of LSMT. Although clinicians may be

the first providers to enter discussion about death and organ donation with family members during conversations about outcomes and options, detailed discussion of organ donation should be done by other individuals who are specifically trained for this purpose. This "decoupling" of clinical decision making from a request for organ donation by trained individuals, perhaps by providing families with expert information without a perceived conflict of interest, has been associated with improved donation rates.

Death by Neurologic Criteria

Death by neurologic criteria (DBNC), commonly referred to as brain death, may be difficult for families to understand when the child appears to be breathing (albeit on a ventilator), pink, and warm to the touch, and when language such as life support is used at the bedside by staff. Studies also document clinician misunderstanding of the diagnosis of DBNC. For these reasons, strict criteria adhering to nationally accepted guidelines must be used to determine when irreversible cessation of brain and brainstem function has occurred, and to adequately document these findings (see Chapter 68.1).

The states of New York and New Jersey allow families to object on religious grounds to the declaration of DBNC. In that situation, the clinical determination of the DBNC sets the stage for a discussion of forgoing LSMT, rather than the death of the patient. A unilateral decision not to initiate new or escalate existing interventions is ethically supportable under these circumstances, given the documented death of the patient. Even though it would seem to follow that a similar unilateral decision to withdraw existing interventions would also be supportable, this act is not in accordance with the intent of the state laws. Institutional procedures for conflict resolution, including involvement of the courts if necessary, should be followed.

Circulatory Death

Protocols allowing for organ donation after determination of circulatory death (DDCD) rather than after DBNC have been developed. DDCD can occur under either controlled (after planned withdrawal of LSMT) or uncontrolled (after failed CPR) circumstances, but in both cases require rapid removal of organs in order for subsequent transplantation to be successful. An increasing number of programs are pursuing DDCD protocols after federal legislation began requiring accredited hospitals to address the issue in hopes of decreasing organ shortages. Hospitals can make policy that either allows or disallows the process. In adults, consent for donation by either means can be obtained from patients or surrogates; for children, parents or guardians would make the decision to donate.

Ethical concerns about DDCD protocols focus on two principles that have served as the basis for organ donation: (1) the "dead donor rule" limiting the donation of vital organs to those who are irreversibly dead (either by circulatory or neurologic criteria, not both), and (2) the absence of conflict of interest between clinical care and organ procurement. With DDCD protocols, irreversibility has been declared at varying times after asystole occurs (usually 2-5 min), to avoid spontaneous return of circulation after forgoing CPR. To avoid a potential conflict of interest during the DDCD process, there is a requirement for strict decoupling of end-of-life care after discontinuation of LSMT and presence of the transplant team. Unlike in the setting of DBNC, a patient who is being considered for DDCD remains alive until after asystole has occurred. Careful evaluation by the transplantation team and organ procurement agency is performed before discontinuation of LSMT. Then, in most DDCD protocols the medical caregivers from the ICU continue to care for the patient until after death by cardiac criteria has been declared, and only then is the surgical transplant team allowed into the room to procure organs.

It is ***ethically imperative*** to correctly diagnose the state of death, whether by neurologic criteria or prior to organ donation after cardiac death. Doing so avoids the danger of removing life-sustaining organs from a living person. Strict adherence to an ethically sound protocol is the best way to prevent both the perception and the potential reality of mistakes related to the pronunciation of death and organ procurement.

RELIGIOUS OR CULTURAL OBJECTIONS TO TREATMENT

Differences in religious beliefs or ethic-based cultural norms may lead to conflict between patients, families, and medical caregivers over the approach to medical care. Pediatricians need to remain sensitive to and maintain an attitude of respect for these differences, yet recognize that an independent obligation exists to provide effective medical treatment to the child. An adult with decision-making capacity is recognized as having the right to refuse treatment on religious or cultural grounds, but children who have not yet developed this capacity are considered a vulnerable population that has a right to treatment. In situations that threaten the life of the child or that may result in substantial harm, legal intervention should be sought if reasonable efforts toward collaborative decision making are ineffective. If a child's life is imminently threatened, medical intervention is ethically justified despite parental objections.

PEDIATRIC ETHICS COMMITTEES AND ETHICS CONSULTATION

Most hospitals have institutional ethics committees to assist with policy development, education, and case consultation. When these committees serve institutions caring for children, they may be referred to as *pediatric ethics committees*. Because of the important differences in approach between adult and pediatric ethics, member expertise on this committee should include those with special insight into the unique ethical issues arising in the care of children. Such committees generally provide ethics consultation advice without mandating action or being determinative. For the vast majority of decisions involving the medical treatment of children (including forgoing LSMT), pediatric clinicians and parents are in agreement about the desirability of the proposed intervention. Because of the ethical importance of assent, the views of older children should also be given considerable weight.

Pediatric ethics committees typically perform at least 3 different functions: (1) the drafting and review of institutional policy on such issues as DNAR orders and forgoing LSMT; (2) the education of healthcare professionals, patients, and families about ethical issues in healthcare; and (3) case consultation and conflict resolution. Although the process of case consultation may vary, ideally the committee (or consultant) should adopt a collaborative approach that uncovers all the readily available and relevant facts, takes into account the values of those involved, and balances the relevant interests, while arriving at a recommendation based on a consistent ethical analysis. One helpful approach involves consideration of the 4 following elements: (1) medical indications, (2) patient preferences, (3) quality of life, and (4) contextual features. Another framework based on principles would suggest attention to respect for persons, beneficence/nonmaleficence, and justice. Pediatric ethics committees often play a constructive role when parents and medical staff cannot agree on the proper course of action. Over the past several decades, these committees have acquired considerable influence and are increasingly recognized by state courts as an important aid in decision making. The membership, policies, and procedures of a pediatric ethics committee should conform to accepted professional standards.

NEWBORN SCREENING AND GENETIC TESTING

The *Oxford Dictionary of Public Health* defines **screening** as "the identification of a previously unrecognized disease or disease precursor, using procedures or tests that can be conducted rapidly and economically on large numbers of people with the aim of sorting them into those who may have the condition(s)…and those who are free from evidence of the condition(s)." Several programs, such as newborn screening for inborn errors of metabolism (see Chapter 84; e.g., phenylketonuria and hypothyroidism), are rightly counted among the triumphs of contemporary pediatrics. The success of such programs sometimes obscures serious ethical issues that continue to arise in proposals to screen for other conditions for which the benefits, risks, and costs have not been clearly established. Advances in genetics and technology have led to exponential growth in the number of conditions

for which screening programs might be considered, with insufficient opportunity to study each proposed testing program (see Chapter 78).

The introduction of screening efforts should be done in a carefully controlled manner that allows for the evaluation of the costs (financial, medical, and psychologic) and benefits of screening, including the effectiveness of follow-up and treatment protocols. New programs should be considered experimental until the risks and benefits can be carefully evaluated. Screening tests that identify candidates for treatment need to have demonstrated sensitivity, specificity, and high predictive value, lest individuals be falsely labeled and subject to possibly toxic treatments or to psychosocial risks. As newborn screening tests are being developed, parents should be given the opportunity to exercise informed parental permission or refusal. However, once a particular screening test has been clearly demonstrated to benefit the individual or public health, a formal, active parental permission process may not be ethically obligatory.

A persistent ethical issue is whether screening should be (1) voluntary ("opt in"), (2) routine, with the ability to "opt out" or refuse, or (3) mandatory. A voluntary approach entails an informed decision by parents before screening. Concern is often expressed that seeking parental permission is ethically misguided for tests of clear benefit, such as phenylketonuria screening, because refusal would constitute neglect. Routine testing with an opt-out approach requires an explicit refusal of screening by parents who object to this intervention. The principal ethical justification for mandatory screening is the claim that society's obligation to promote child welfare through early detection and treatment of selected conditions supersedes any parental right to refuse this simple and low-risk medical intervention. Parental permission is clearly required when there is a research agenda (i.e., for incorporating experimental tests into established screening programs).

Genetic testing of young children for late-onset disorders such as the *BRCA1* and *BRCA2* breast cancer risk genes has been the subject of some ethical controversy. Knowledge of increased risk status may lead to lifestyle changes that can reduce morbidity and the risk of mortality, or may precipitate adverse emotional and psychologic responses and discrimination. Because many adults choose not to be tested for late-onset disorders, one cannot assume that a child would want or will benefit from similar testing. Genetic testing of young children for late-onset disorders is generally inappropriate unless such testing will result in interventions that have been shown to reduce morbidity and mortality when initiated in childhood. Otherwise, such testing should be deferred until the child has the capacity to make an informed and voluntary choice. This ethical approach is founded on the work of philosopher Joel Feinberg's writing on the "child's right to an open future."

ADOLESCENT HEALTHCARE

Adolescent Assent and Consent

Many adolescents are more like adults than children in their capacity to understand healthcare issues and to relate them to their life goals (see Chapter 110). Teenagers may lack legally defined competency, yet they may have developed the capacity meet the elements of informed consent for many aspects of medical care (see Chapter 112). There are also public health reasons for allowing adolescents to consent to their own healthcare with regard to reproductive decisions, such as contraception, abortion, and treatment of sexually transmitted infections. Strict requirements for parental permission may deter adolescents from seeking healthcare, with serious implications for their health and other community interests.

Counterbalancing these arguments are legitimate parental interests to maintain responsibility and authority for child rearing, including the opportunity to influence the sexual attitudes and practices of their children. Others claim that access to treatment such as contraception, abortion, or needle exchange programs implicitly endorses sexual activity or drug use during adolescence. Pediatricians should not impose their own moral beliefs in these disputes. Rather, they should provide unbiased evidence-based information and nonjudgmental support. One guiding principle should be encouragement of children and adolescents to begin taking responsibility, with guidance, for their own health. This requires some input from parents or guardians but also some privacy during decision making as they achieve developmentally anticipated separation from parental control.

Chronic Illness

The normal process of adolescent development involves gradually separating from parents, establishing self-confidence, asserting individuality, developing strong peer relationships, solidifying an ability to function independently outside the family, and taking on increasing autonomy in healthcare decisions. Most developmentally normal children older than age 14 yr understand the implications of well-explained medical options as well as the average adult, and their input into their own care should be respected. For children living with chronic illness, the ability to make medical decisions for themselves may either occur earlier than for those who have been previously healthy, or may occur later if, because of illness, they have not been able to achieve normal developmental milestones or psychological maturity. The clinician's role involves assessment of the individual adolescent patient's ability to understand the medical situation, to support the patient's efforts to express wishes regarding medical treatment, to value and encourage parental support and involvement, and to foster cooperation and mutual understanding. This may be difficult in situations in which parents and adolescents disagree about life-sustaining treatments such as organ transplantation or chemotherapy, but many such conflicts may be resolved by exploring the reasons for the disagreement. Overriding an adolescent's wishes should be done very infrequently, and only after careful consideration of the potential consequences of unwanted interventions.

Decisions in Terminally Ill Adolescents

Most adolescents share end-of-life decision making with family members, although communication may be challenging because of a growing sense of independence. Open communication and flexibility about treatment preferences may help teens cope with fears and uncertainties. Development of an age-appropriate AD may support the patient's emerging autonomy by clarifying the adolescent's wishes, while fostering a collaborative process among the patient, family, and medical caregivers. From the time of diagnosis of a life-threatening condition through the end-of-life phase, children should be included in a developmentally tailored process of communication and shared decision-making that builds a foundation of mutual respect and trust.

RESEARCH

The central ethical challenge of pediatric research is the need to balance protection of children from research risk against the ethical imperative of conducting studies to better the lives of future children. Research is defined in the federal regulations as "a systematic investigation designed to develop or contribute to generalizable knowledge." For any research to be performed, the risks should be minimized and reasonable with respect to any anticipated benefits to the subjects and the importance of the resulting knowledge. The fact that some children derive a direct benefit from participation in research must also be considered, making it important to distinguish research with the prospect of direct benefit from nontherapeutic pediatric research. ***Because children are a vulnerable population, there are restrictions on the research risks to which a child may be exposed*** that contrast with the risk level acceptable for research with consenting adults. These restrictions function by limiting the kind of research institutional review boards (IRBs) are permitted to approve and by specifying the conditions under which parent(s) have the moral and legal authority to permit a child to participate in research.

Nontherapeutic research in children is the most ethically controversial because it holds no expected direct benefit for the subject. The prohibition against using a person (especially a child) solely as a means to an end has led some to argue that children should never be used in nontherapeutic research. The more widely held opinion is that children may be exposed to a limited degree of risk with IRB approval, parental permission, and assent if the child is capable. The federal regulations allow healthy children to participate in minimal-risk research regardless of the potential benefit to the child-subject. More

controversially, the regulations also state that children with a disorder or condition may be exposed to slightly more than minimal risk in nontherapeutic research if the child's experience is similar to everyday life with that condition and the anticipated knowledge is of vital importance for understanding that condition.

In pediatric research with the prospect of direct benefit, the risks must be justified by the anticipated benefit to the child, and the balance of anticipated benefit to the risk should be at least as favorable as that presented by available alternatives. ***The welfare of an individual child must always come before the scientific goals of the research study.***

The regulations in the United States for the protection of human research subjects rest on 2 foundations: (1) independent review of the ethics and science of the research by an IRB **prior to** (2) voluntary and informed consent of the subject/participant. Although it is not amenable to regulation, the integrity of the investigator is probably the most important element contributing to the protection of human research subjects. The standard for informed consent in a research setting is higher than for clinical care because the risks and benefits are typically less clear, the investigator has a conflict of interest, and humans have historically been subjected to unauthorized risks when strict requirements for consent were not respected.

Adolescents who are competent may sometimes consent to be research subjects. Younger children may participate in a process of assent, but this does not imply that a child's signature on an assent document is necessarily a legal or ethical requirement. Children should be given the opportunity to dissent, particularly for nontherapeutic research, when there cannot be a claim that participation is in the child's interest. In the United States, national regulations require that reasonable efforts be made at least to inform children who are capable of understanding that participation is not part of their care and that, therefore, they are free to refuse to participate. In the rare case that the research offers a direct benefit to the child that would not otherwise be available, the regulations do not require child assent but only parental permission.

In addition to the protection that informed consent/parental permission is intended to provide, virtually all research involving human subjects in the United States is reviewed by an IRB, required by federal regulations for institutions receiving federal research funds and for drug research regulated by the U.S. Food and Drug Administration. For research that carries more than a minor increase over minimal risk without prospect of benefit to the child such that a local IRB cannot provide approval, there is a process for federal review of research that "presents a reasonable opportunity to further the understanding, prevention, or alleviation of a serious problem affecting the health or welfare of children." Ultimately, the U.S. Secretary of Health and Human Services has the authority to approve such research.

BALANCING MATERNAL AND FETAL INTERESTS

Some situations require balancing of maternal health and well-being with those of the fetus/unborn child to reach an ethically sound decision. For instance, innovative surgical treatment of a prenatally diagnosed anomaly may help the fetus/unborn child survive, but in the process place the mother at risk of injury or of loss of the pregnancy. Alternatively, a pregnant woman may object to delivery by caesarian section for various reasons in spite of advice that it may protect the fetus/unborn child during birth. A third important situation involves risk-taking behaviors during pregnancy that are known to injure the developing fetus/unborn child, such as drug or alcohol use. These issues raise conflicts over clinicians' responsibility to the living, competent decision-maker—the pregnant mother—as opposed to the interests of the fetus/unborn child.

In certain cases, courts in the United States have decided that a woman can be required to undergo caesarian section against her will when the risk to her health is minimal and the benefit to the otherwise normal, near-term fetus/unborn child is clear, for example, in a case of placenta previa. Other factors, such as prematurity, have led to the opposite legal conclusion in otherwise similar situations because the benefit of intervention was less clear. In general, a clinician should not oppose a pregnant woman's refusal of a recommended intervention unless (1) the risk to the pregnant woman is minimal, (2) the intervention is clearly effective, and (3) the harm to the fetus/unborn child without the intervention would be certain, substantial, and irrevocable. Attempts should be made to persuade the pregnant woman to comply with recommendations in the interest of the fetus/unborn child when these 3 conditions exist, using support strategies such as the influence of other trusted caregivers, clergy, and/or ethics consultation/committee involvement. If these approaches fail and there is time, a clinician may seek judicial intervention as a last resort in the attempt to prevent harm to the fetus/unborn child.

Obstetricians and pediatricians may consider reporting women under child abuse or neglect statutes if ingesting alcohol or illicit drugs during pregnancy is felt to place the fetus/unborn child at risk of injury. However, clinicians must consider the likelihood of benefit from reporting, the harm to the child as well as to the mother if criminal charges or custody changes are sought, and the possible effects that reporting may have on driving pregnant women away from prenatal or postnatal care. The U.S. Supreme Court has held that drug testing of pregnant women without consent was a violation of the Fourth Amendment, which provides protection from unreasonable searches.

JUSTICE AND PEDIATRIC ETHICS

The most serious ethical problem in healthcare in the United States may be inequality in access to healthcare. Children are particularly vulnerable to this disparity, and pediatricians have a moral obligation to advocate for children as a class. Because children do not vote and do not have financial resources at their disposal, they are subject to a greater risk of being uninsured or underinsured. This lack of adequate and affordable healthcare has serious consequences in terms of death, disability, and suffering. The Affordable Care Act may help to ameliorate these problems in the United States. The per capita proportion of healthcare funding spent on adults greatly exceeds that spent on children, and Medicare is available to all adults who turn 65 yr old whereas Medicaid is limited to those beneath a specific income level. Federal dollars intended to support healthcare for children are generally administered and supplemented with state funds, which can create additional barriers. Pediatricians should be familiar with policy issues around the economics of child healthcare so that they will be better able to advocate for their own patients (see Chapter 1).

EMERGING ISSUES

The ready availability of information on the Internet has encouraged parents to become more involved in advocating for specific approaches to the healthcare of their children, requiring physicians to remain aware of the quality of these sources of information in order to adequately counsel parents on treatment choices. Because the range of aggressive, innovative, or exceedingly expensive therapies has increased, without necessarily providing clear benefit to the patient, pediatricians must exercise care and judgment before agreeing to pursue these interventions. A growing number of parents are refusing to immunize their children because of fear of adverse reaction to vaccine. This raises the ethical problem of the "free rider," in which a child may benefit from herd immunity because others have been immunized without contributing to this public good. Outbreaks of preventable infectious disease have been detected in communities where vaccine refusal is prevalent. Pediatricians should manage this issue with ethical sensitivity, educating parents about the safety profile of vaccines and encouraging appropriate immunization. More confrontational approaches are not generally effective or ethically warranted. A second emerging issue relates to children as stem cell or solid organ donors. Here the risk : benefit balance should be carefully weighed, but in general, a permissive policy with regard to stem cell donation and a more restrictive approach to solid-organ donation are ethically justified. Finally, controversial medical and surgical interventions, such as growth attenuation of children with severe cognitive impairment in hopes of prolonging ability to care for them in the home setting, and disorders of sexual development require careful ethical consideration. Attitudes about emerging technologies and treatments

may be influenced by media coverage, special interest groups, and efforts by understandably desperate families to help their children. The clinician attempting to practice ethically must carefully consider all relevant facts in each case, and try to focus families and caregivers on a reasonable best interest assessment for the child. The tension between finding optimal policy for groups of children and doing the right thing for an individual child raises formidable ethical challenges in this context. Ethics consultation may be helpful to frame the issues and design ethically supportable approaches to care.

Chapter 4

Cultural Issues in Pediatric Care

Linda Kaljee and Bonita F. Stanton

Pediatricians live and work in a multicultural world. Among the world's 7 billion people residing in >200 countries, >6,000 languages are spoken. As the global population becomes more mobile and integrated, ethnic and economic diversity increases in all countries. From 1970 to 2000, the foreign-born population in the United States increased 3-fold. In the 2000 U.S. census, 25-30% of Americans self-identified as belonging to an ethnic or racial minority group. In 2010, 13% of the population was foreign born and 1 or both parents of 24% of children under age 17 yr is foreign born; the 40 million immigrants represents a 28% increase over the number in 2000. Whereas in 1920, 97% of immigrant families in the United States were from Europe or Canada as of 2010 more than 90% of immigrant families are from Asia and Latin America. Nonwhite children are projected to outnumber white children in the United States by the year 2030. Increased migration and diversity in the migrant pool is not limited to the United States; immigrants account for more than 15% of the population in >50 nations.

THE IMPORTANCE OF CULTURE TO MEDICAL PRACTICE

The concept of culture includes the ways in which a group of people share and understand their history, beliefs, and values, and engage in behaviors reflective of these shared worldviews. Although culture is not synonymous with language, ethnicity, nationality, or socioeconomic status, groups with similar backgrounds with respect to these characteristics often share cultural norms and beliefs.

Within cultures, there are frameworks for classifying and organizing kin (family), assigning roles and responsibilities based on age, gender, and other social groupings, and defining concepts such as prosperity, success, knowledge, causes of disease, and health. Disease typology, prevention and intervention efforts, and health practitioners are culturally defined. Health-related cultural-beliefs and practices are integrated within pluralistic health systems that include both biomedicine and traditional medicine.

Tables 4-1 to 4-3 display some cultural values associated with 4 populations in the United States: Latinos, Muslims, Native Americans, and African-Americans, illustrating both areas of significant overlap and great variation that are relevant to health perceptions and health seeking. Latinos may subscribe to the importance of "personalismo," placing great importance on politeness in the face of stress and adversity. Thus expectations may include a display of warmth from their physician, including physical touching such as handshaking, placing hands on the shoulder, and occasionally hugging. By contrast, in the Muslim culture, for a person to touch the body of a member of the opposite gender, including on the arm or a pat on the shoulder, is considered highly inappropriate.

Despite the existence of shared values within a defined population group, there may be substantial variations within subgroups, such as the Latino national subgroups (e.g., Cuban, Puerto Rican, Dominican, Mexican), resulting in great variation in specific health-seeking behaviors. Likewise, within an overarching culture ("American"), persons who are economically and/or politically disenfranchised may use resistance, inverting the values of the dominant socioeconomic group. Such a reaction may include distrust of recommendations regarding healthcare from members of the perceived dominant or controlling group or class. Immunizations have been viewed with distrust among the poor in countries around the globe, as they were believed to be a form of birth control or sterilization and were often offered through institutions associated with "Western" and postcolonial rule. Within cultures, socially constructed categories of gender, sexuality, and age affect perceptions of an individual's vulnerability to a particular disease or condition, as well as the individual's access to health system resources. Adolescents girls living in cultures with strong taboos against premarital sexual relationships (e.g., Chinese, Muslim, Vietnamese) may not have social access to disease and birth control protection (e.g., condoms) resulting in increased risks for HIV, other sexually transmitted infections, and unwanted pregnancies.

There may also be significant generational differences between foreign-born parents and their American-raised children, particularly as these children go through adolescence. Such disparate experiences and cultural identities can result in a generational gap that decreases parent–child communication and subsequently lessens the important positive effects of communication on reducing substance use and engagement in sexual risk behaviors among youth.

Other values may be shared across disparate cultural groups. Multiple ethnic groups, including Latinos and Muslims, as well as Sudanese and Bengalis, share a cultural belief of fatalism, with strong implications for health-seeking behavior.

The perceived role of the physician may also differ between cultures. Pediatricians are trained to offer advice on child rearing, and studies have shown that parents look to pediatricians for this advice. However, parents of differing cultural backgrounds may not desire or may be reluctant to accept such advice.

NEWLY RECOGNIZED CULTURAL GROUPS

Groups that may or may not traditionally have been recognized as distinct cultural groups, (adolescents, gay/lesbian youth, transgender youth, street youth, deaf youth, etc.) have shared values which frequently have implications for health and health seeking. Failure on the part of the pediatrician to recognize accepted language and frame of reference of these groups may result in the unintentional use of offensive terminology or assumptions, leading to loss of the physician's credibility or noncompliance from the patient.

THE CULTURE OF THE MEDICAL PROFESSION

The profession of medicine also has a distinct culture. Like other cultural groups, physicians have a distinct "language" and share a common history, admiring the same role models, sharing the same preparatory courses that must be mastered for entrance into training for the profession, and subscribing to a common meaning of "competence" in medical practice. Physicians learn a new way to describe health and illness, requiring a new vocabulary and a prescribed pattern to the narrative history, which is not shared by those outside medicine. Physician reliance on "evidence-based practice" carries the implication that it is synonymous with truth or real knowledge. Of particular importance in the relationship with patients has been the lack of physician insight into the existence of a physician culture and the potential biases that may be inherent to that culture.

Although physicians around the world recognize the great strides that have been made in child survival through the use of oral rehydration therapy in the treatment of dehydrating diarrheal diseases, parents are often anxious because the treatment does not stop the diarrhea. Physicians may be dependent on a particular style of communication

Table 4-1 Cultural Values* Relevant to Health and Health-Seeking Behavior

CULTURAL GROUP	RELEVANT CULTURAL NORMS	
	Description of Norm	**Consequences of Failure to Appreciate**
Latino	*Fatalismo:* Fate is predetermined, reducing belief in the importance of screening and prevention	Less preventive screening
	Simpatia: Politeness/kindness in the face of adversity—expectation that the physician should be polite and pleasant, not detached	Nonadherence to therapy, failure to make follow-up visits
	Personalismo: Expectation of developing a warm, personal relationship with the clinician, including introductory touching	Refusal to divulge important parts of medical history, dissatisfaction with treatment
	Respecto: Deferential behavior on the basis of age, social stature, and economic position, including reluctance to ask questions	Mistaking a deferential nod of the head/not asking questions for understanding; anger at not receiving due signs of respect
	Familismo: Needs of the extended family outrank those of the individual, and thus family may need to be consulted in medical decision making	Unnecessary conflict, inability to reach a decision
Muslim	*Fasting* during the holy month of Ramadan: fasting from sunrise to sundown, beginning during the teen years. Women are exempted during pregnancy, lactation, and menstruation, and there are exemptions for illness, but an exemption may be associated with a sense of personal failure	Inappropriate therapy; will not take medicines during daytime misinterpreted as noncompliance; misdiagnosed
	Modesty: Women's body including hair, body, arms, and legs not to be seen by men other than in immediate family. Female chaperone and/or husband must be present during exam and only that part of the body being examined should be uncovered	Deep personal outrage, seeking alternative care
	Touch: Forbidden to touch members of the opposite sex other than close family. Even a handshake may be inappropriate	Patient discomfort, seeking care elsewhere
	After death, body belongs to God: Postmortem exam will not be permitted unless required by law; family may wish to perform after-death care	Unnecessary intensification of grief and loss
	Cleanliness essential before prayer: Individual must perform ritual ablutions before prayer, especially elimination of urine and stool. Nurse may need to assist in cleaning if patient is incapable	Affront to religious beliefs
	God's will: God causes all to happen for a reason, and only God can bring about healing	Allopathic medicine will be rejected if it conflicts with religious beliefs, family may not seek healthcare
	Patriarchal, extended family: Older male typically is head of household, and family may defer to him for decision making	Child's mother or even both parents may not be able to make decisions about child's care; emergency decisions may require additional time
	Halal (permitted) vs. *harem* (forbidden) foods and medications: Foods and medicine containing alcohol (some cough and cold syrups) or pork (some gelatin-coated pills) are not permitted	Refusal of medication, religious effrontery
Native American	*Nature* provides the spiritual, emotional, physical, social, and biologic means for human life; by caring for the earth, Native Americans will be provided for. Harmonious living is important	Spiritual living is required of Native Americans; if treatments do not reflect this view, they are likely not to be followed
	Passive forbearance or right of the individual to choose his or her path: Another family member cannot intervene	Mother's failure to intervene in a child's behavior and/or use of noncoercive disciplinary techniques may be mistaken for neglect
	Natural unfolding of the individual: Parents further the development of their children by limiting direct interventions and viewing their natural unfolding	Many pediatric preventive practices will run counter to this philosophy
	Talking circle format to decision-making: Interactive learning format including diverse tribal members	Lecturing, excluding the views of elders is likely to result in advice that will be disregarded
African-American	Great heterogeneity in beliefs and culture among African-Americans	Risk of stereotyping and/or making assumptions that do not apply to a specific patient or family
	Extended family and variations in family size and child care arrangements are common; matriarchal decision making regarding healthcare	Advice/instructions given only to the parent and not to others involved in health decision making may not be effective
	Parenting style often involves stricter adherence to rules than seen in some other cultures	Advice regarding discipline may be disregarded if it is inconsistent with perceived norms; other parenting styles may not be effective
	History-based widespread mistrust of medical profession and strong orientation toward culturally specific alternative/complementary medicine	In patient noncompliance, physicians will be consulted as a last resort
	Greater orientation toward others; the role of an individual is emphasized as it relates to others within a social network	Compliance may be difficult if the needs of 1 individual are stressed above the needs of the group
	Spirituality/religiosity important; church attendance central in most African-American families	Loss of opportunity to work with the church as an ally in healthcare

Table 4-1 Cultural Values* Relevant to Health and Health-Seeking Behavior—cont'd

CULTURAL GROUP	RELEVANT CULTURAL NORMS	
	Description of Norm	**Consequences of Failure to Appreciate**
East and Southeast Asian	Long history of eastern medicines (e.g., Chinese medicine) as well as more localized medical traditions	May engage with multiple health systems (Western biomedical and traditional) for treatment of symptoms and diseases
	Extended families and care networks. Grandparents may provide day-to-day care for children while parents work outside of the home	Parents may not be the only individuals a physician needs to communicate with in regard to symptoms, follow-through on treatments, and preventive behaviors
	Sexually conservative. Strong taboos for premarital sexual relationships, especially for women	Adolescents may be reluctant to talk about issues of sexuality, pregnancy, birth control with physicians. Recent immigrants or native populations may have less knowledge regarding pregnancy prevention, sexually transmitted infections, and HIV.
	Infant/child feeding practices may overemphasize infant's or child's need to eat a certain amount of food to stay "healthy"	Guidelines for child nutrition and feeding practices may not be followed out of concern for child's well-being
	Saving face. This is a complex value whereby an individual may lose prestige or respect of a third party when a second individual says negative or contradictory statements	Avoid statements that are potentially value laden or imply a criticism of an individual. Use statements such as "We have now found that it is better to …" rather than criticizing a practice

*Adherence to these or other beliefs will vary among members of a cultural group based on nation of origin, specific religious sect, degree of acculturation, age of patient, etc.

Table 4-2 Examples of Disease Beliefs or Practices

CULTURAL GROUP	EXAMPLES
Latino	Use of traditional medicines (nopales or cooked prickly pear cactus as a hypoglycemic agent) along with allopathic medicine Recognition of disorders not recognized in Western allopathic medicine (*empacho*, in which food adheres to the intestines or stomach), which are treated with folk remedies but also brought to the pediatrician Cultural interpretation of disease (*caida de mollera* or fallen fontanel) as a cultural interpretation of severe dehydration in infants
Muslim	Female genital mutilation: practiced in some Muslim countries; the majority do not practice it and it is not a direct teaching of the Koran Koranic faith healers: use verses from the Koran, holy water, and specific foods to bring about recovery
Native American	Traditional "interpreters" or "healers" interpret signs and answers to prayers. Their advice may be sought in addition or instead of allopathic medicine Dreams are believed to provide guidance; messages in the dream will be followed
East and Southeast Asian	Concepts of "hot" and "cold," whereby a combination of hot and cold foods and other substances (e.g., coffee, alcohol) combine to cause illness. One important aspect is that Western medicines are considered hot by Vietnamese and, therefore, nonadherence may occur if it is perceived that too much of a medicine will make their child's body hot. *Note:* Hot and cold do not refer to temperatures, but are a typology of different foods; for example, fish is hot and ginger is cold. Foods, teas, and herbs are also important forms of medicine because they provide balance between hot and cold

and they may miss information from patients using alternative narrative styles. Likewise, the physician–researcher forms questions through the prism of the physician–researcher's own beliefs and literature, thereby reducing the likelihood of exploring alternative explanations or questions. Even though vast segments of the world's population understand disease as an imbalance of "hot" and "cold," this belief system has not been well-represented in contemporary medical research.

CULTURAL COMPETENCE

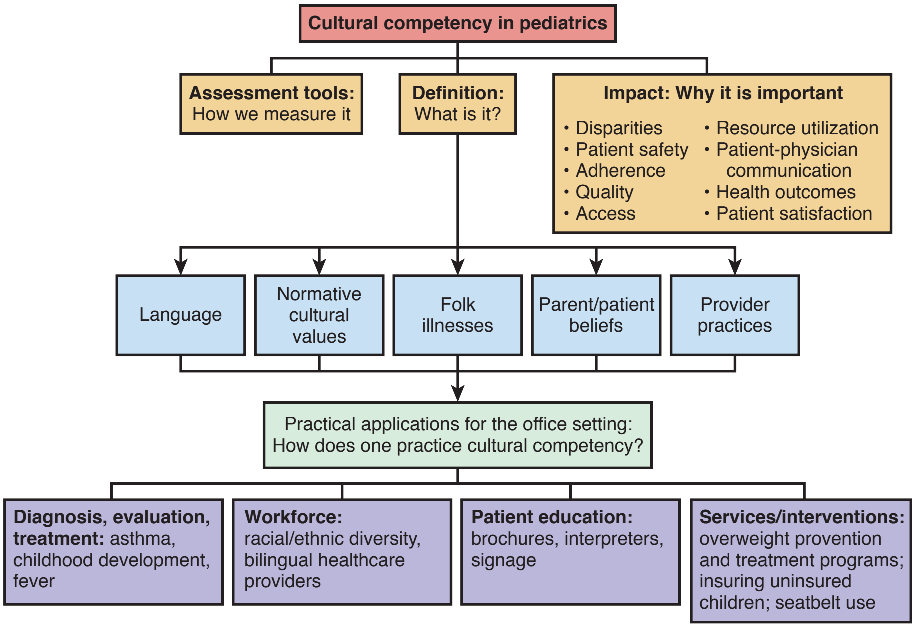
Physicians and patients bring to their interaction personal and professional values from multiple cultural systems that have significant implications for the delivery of healthcare. Consequently, physician "cultural competence" is critical to a successful patient–provider interaction (Fig. 4-1). Campinha-Bacote's model for understanding and assessing culturally competency is frequently used in education and research: (1) learning to value and understand other cultures, in part through self-awareness of one's own cultural values ("cultural awareness"); (2) learning basic fundamentals about other cultures, particularly those of the patients with whom the physician will interact ("cultural knowledge"); (3) developing the ability to apply cultural knowledge in patient encounters ("cultural skills"); (4) seeking exposure to cross-cultural interactions ("cultural encounters"); and (5) being motivated to achieve all of the previous ("cultural desire"). This framework provides an important guide to pediatric education and practice and, thus, will serve as the outline for the remainder of this chapter.

Cultural Awareness

Recognition of the importance of differing cultural expectations and explanations is critical to a pediatrician's successful interactions with patients. Among many cultures (e.g., Muslim), kinship is of great importance and decision making may involve the extended family. The erroneous belief on the part of a physician that a mother may execute independent decision making in relation to her child's healthcare (when in fact she may not be entitled to such a role in her family or culture) may result in an apparent noncompliance on the part of the mother.

Cultural Knowledge

Physicians and patients have differing definitions of health and illness and differing concepts of the origins of disease and therapeutic responses. Understanding the patient perspective will both increase



Conceptual framework for cultural competency in pediatrics: (1) what is known about the impact of cultural competency on general pediatric care; (2) the domains of cultural competency; and (3) practical applications of cultural competency for general pediatricians

Figure 4-1 Components of cultural competency in pediatric practice. *(From Brotanek JM, Seeley CE, Flores G: The importance of cultural competency in general pediatrics,* Curr Opin Pediatr *20:711–718, 2008, Fig. 1, p. 712.)*

Table 4-3 Home Remedies for Fever, Colic, and Teething Among African-Americans

CONDITION	REMEDY	KNOWLEDGE, % (N = 107)	USE, % (N = 107)
Fever	Acetaminophen*	98	77.6

*Responses given in closed-ended questions.
†Responses given in open-ended questions.
From Smitherman LC, Janisse J, Mathur A: The use of folk remedies among children in an urban black community: remedies for fever, colic and teething, Pediatrics 115:297–304, 2005, Table 2.

the likelihood of correct diagnosis and patient adherence to therapy and decrease the possibility of misdiagnosis. The belief that becoming chilled causes dysentery is common among rural Chinese, and medical advice that directly challenges or runs contrary to this belief may be disregarded. Likewise, diarrhea among Bangladeshi children during teething may be regarded as normal and would not be identified as a health issue. Thus, asking the parent if the child has been ill might not reveal the presence of diarrhea. Rubbing a coin against a child's skin is thought by some parents in Asia to reduce fever. Failure by the pediatrician to recognize the practice of *coining* could lead to the erroneous

diagnosis of a rash or child abuse. In some instances, particularly in relation to developmental and emotional disorders, the manifestation of symptoms and/or recognition of symptoms by parents or other caregivers may be culturally defined. Autism is a condition characterized by communication and socializing disabilities. Yet expectations of children's language and social skills development are culturally defined, resulting in potentially later identification by family members of a child's disabilities and subsequently delayed treatment seeking.

Cultural Skill

Describing a diagnostic or therapeutic course of action that respects cultural beliefs but is consistent with good medical practice can be challenging. Common among many Latino groups is the belief of *empacho,* a condition wherein food is "stuck" to the stomach or intestinal wall, resulting in obstruction. The condition is believed to cause nausea, vomiting, diarrhea, and anorexia. Although many Latino parents would take a child with *empacho* to the physician for treatment, in Western settings, a pediatrician diagnosing the condition as viral gastroenteritis might only advise supportive management, leaving the parents perplexed and with no option but to seek independent treatment from an alternative or traditional healer. A culturally skilled pediatrician might suggest partnering with the traditional healer in such a situation. Likewise, in response to parents subscribing to a belief in fatalism and, consequently, a notion that preventive medicine or screening is not necessary, a skilled pediatrician might suggest that screening is the mechanism through which their destiny is intended to be reached. Referrals for services may also be affected by a patient's culture and history. The need for psychologic services may be rejected because of cultural stigmas regarding psychological disorders. Likewise, referrals for HIV or sexually transmitted infection testing may be more likely rejected by gay adolescent men from cultures in which homosexuality is highly stigmatized.

Central to "cultural skill" is the employment of language fully comprehended by the child's parents. This goal is best realized if the pediatrician is at least conversant in the parent's language, and thus a requirement for a second language is a reasonable goal for physicians. Familiarity with a language should not be confused with fluency or even competency. Professional interpreters should be available and accessed to overcome the language barriers. Ad hoc use of individuals at the workplace who are known to possess skill in the indicated language and/or use of telephone interpreter services may suffice if a professional interpreter is not available. A genuinely bilingual family member or friend may be helpful, but issues of confidentiality, disruption of social roles, and uncertain or inaccurate translation of medical terms may pose serious problems. Medical errors occur at a significantly higher rate among non–English speaking patients when nonprofessional translators (e.g., family members) are used to obtain a history or give medical advice.

Cultural Encounters

Although cultural knowledge may be acquired through didactic training, the development of cultural skills requires experience that can only be gained through repeated "cultural encounters." Nonminority clinicians provide lower quality of care to Latino and African-American patients, with these children being less likely to receive analgesia and/or nebulizers for asthma. Latino mothers have reported clinician attitudes as a major barrier to seeking care for their children. Participation by physicians in diverse medical educational settings and experience in community clinics has been shown to predict increased cultural knowledge. Cultural knowledge and participation in diverse educational settings, and Latino ethnicity and bilingual skills likewise predict cultural awareness, Cultural awareness predicts culturally competent actions. Consistent with observations that cultural competence may not be valued in the traditional medical culture is the observation that *higher* specialty training (e.g., subspecialty training among internists compared to general physicians, family medicine, or internal medicine generalists) predicted *less* cultural awareness. Children who receive care from practice sites with the highest cultural competence scores are less likely to underutilize preventive asthma medications.

Cultural Desire

Cultural competence is not something that can be achieved and retained in the absence of continued effort. The recognition that culture is integral to health and healing, and to disease and sickness, is central to the concept of "cultural competence." Understanding of the role of culture in health outcomes is nascent; it is not yet known why less acculturated Latinos in the United States demonstrate significantly lower rates of low birthweight, depression, tobacco use, illicit drug use, and older age for sexual debut compared to those who are more acculturated. Likewise, less acculturation among Asian children is associated with lower prevalence of chronic illness. Such findings expose the complexities between individuality, environment, cultures, and biology, and how these integrated factors can affect health-related behaviors and health outcomes.

Chapter 5

Maximizing Children's Health: Screening, Anticipatory Guidance, and Counseling

Joseph F. Hagan Jr. and Paula M. Duncan

Routine, scheduled care of well infants, children, and adolescents is an essential prevention effort for children and youth worldwide. Children's constantly changing development lends added value to regular and periodic encounters between children and their families and practitioners of pediatric healthcare. Health supervision visits from birth to age 21 yr are the platform for a young person's healthcare. The provision of well care in the medical home, fosters strong relationships between the clinic or practice and the child and family, enabling the provision of appropriate surveillance, screening, and sick care.

To assure the optimal health of the developing child, pediatric care in the United States and other countries evolved into regularly scheduled visits to assure adequate nutrition, detect and immunize against infectious diseases, and observe the child's development. Assessment of immunizations, nutrition and developmental status remain essential elements of the well-child health supervision visit, but changes in the population's health have led to the addition of other components to the content of today's well-child encounter. Preventive care for children and youth is a component of contemporary U.S. health reform activities; this approach offers great opportunity for health cost savings.

A healthy economy requires educated and healthy workers. For children to have a successful educational experience, they must have both physical and emotional health. Educational success is also tied to early childhood developmental competence. Thus health supervision well-child care plays a vital role in promoting adult health, a concept endorsed by business leaders.

Adversity impairs development and adverse factors in life experience increase the risk of disease. Adults who experienced abuse, violence, or other stressors as children have an increased risk for depression, heart disease, and other morbidities. Biology informs us that stress leads to increased heart rate and blood pressure, and increased levels of inflammatory cytokines, cortisol, and other stress hormones, all of which impair brain activity, immune status, and cardiovascular function. There are both a causal model and evidence that

adverse childhood events, including those that could have been prevented, adversely impact the life course.

PERIODICITY

The frequency and content for well-child care activities are derived from evidence-based practice and research. In addition, federal agencies and professional organizations, such as the American Academy of Pediatrics (AAP), have developed evidence informed, expert consensus guidelines for care. The Recommendations for Preventive Pediatric Health Care or Periodicity Schedule (Fig. 5-1) is a compilation of recommendations listed by age-based visits. It is intended to guide practitioners of pediatric primary care to perform certain services and make observations at age-specific visits and it designates the standard for preventive services for children and youth according to the U.S. health reform legislation, the Affordable Care Act of 2010.

GUIDELINES

Comprehensive guides for care of well infants, children, and adolescents have been developed, based on the Periodicity Schedule, which expand and further recommend how practitioners might accomplish the tasks outlined in the Periodicity Schedule. In the United States, the current guideline standard is *The Bright Futures Guidelines for Health Supervision of Infants, Children, and Adolescents,* 4th edition. These guidelines were developed by the AAP under the leadership of the Maternal Child Health Bureau of the U.S. Department of Health and Human Services, in collaboration with the National Association of Pediatric Nurse Practitioners, the American Academy of Family Physicians, the American Medical Association, the American Academy of Pediatric Dentistry, Family Voices, and others.

TASKS OF WELL-CHILD CARE

The well-child encounter intends to promote the physical and emotional well-being of children and youth. Child health professionals, including pediatricians, family medicine physicians, nurse practitioners, and physician assistants, take advantage of the opportunity well-child visits provide to elicit parental questions and concerns, gather relevant family and individual health information, perform a physical examination, and initiate screening tests.

The tasks of each well-child visit include:

- Disease detection
- Disease prevention
- Health promotion
- Anticipatory guidance

To achieve these outcomes, healthcare professionals employ techniques to screen for disease, screen for risk of disease, and provide advice about healthy behaviors. These activities lead to the formulation of appropriate anticipatory guidance and health advice.

Clinical detection of disease in the well-child encounter is accomplished by both surveillance and screening. In well-child care, surveillance occurs in every health encounter and is enhanced by repeated visits and observations with advancing developmental stages. It relies on the experience of a skilled clinician over time. Screening is a more formal process utilizing some form of tool that has been validated and has known sensitivity and specificity. For example, anemia surveillance is accomplished through taking a dietary history and seeking signs of anemia in the physical examination. Anemia screening is done by hematocrit or hemoglobin tests. Developmental surveillance relies on the observations of parents and the watchful eyes of providers of pediatric healthcare who are experienced in child development. Developmental screening uses a structured developmental screening tool by personnel trained in its use or in the scoring and interpretation of parent report questionnaires.

The second essential action of the well-child encounter, *disease prevention,* may include both *primary prevention* activities applied to a whole population and *secondary prevention* activities aimed at patients with specific factors of risk. For example, counseling about reducing fat intake is appropriate for all children and families. Counseling is intensified for overweight and obese youth or in the presence of a family history of hyperlipidemia and its sequelae. The child and adolescent healthcare professional needs to individualize disease prevention strategies to the specific patient, family, and community.

Health promotion and **anticipatory guidance** activities distinguish the well-child health supervision visit from all other encounters with the healthcare system. Disease detection and disease prevention activities are germane to all interactions of children with physicians and other healthcare providers, but health promotion and anticipatory guidance shift the focus to wellness and to the strengths of the family (e.g., what is being done well and how this might be improved). This approach is an opportunity to help the family address relationship issues, broach important safety topics, access community services, and engage with extended family, school, neighborhood, and church.

It is not possible to cover all the topics suggested by comprehensive guidelines such as *Bright Futures* in the average 18 min well-child visit. Child health professionals must prioritize the most important topics to cover. Consideration should be given to a discussion of:

- The agenda the parent or child brings to the health supervision visit.
- The topics where evidence suggests counseling is effective in behavioral change.
- The topics where there is a clear rationale for the issue's critical importance to health, for example, sleep environment to prevent sudden infant death syndrome or attention to diet and physical activity.
- A summary of the child's progress in emotional and social development, physical growth, and strengths.
- Issues that address the questions, concerns, or specific health problems relevant to the individual family.
- Community-specific problems that could significantly impact the child's health (e.g., neighborhood violence from which children need protection or absence of bike paths that would promote activity).

It is important to note that this approach is directed at all children, including those with special health needs. Children with special health needs are no different from other children in their need for guidance about healthy nutrition, physical activity, progress in school, connection with friends, a healthy sense of self-efficacy, and avoidance of risk-taking behaviors. The coordination of specialty consultation, medication monitoring, and functional assessment, which should occur in their periodic visits, needs to be balanced with a discussion of the child's unique ways of accomplishing the emotional, social, and developmental tasks of childhood and adolescence. Comprehensive integrated care planning for children and youth with special healthcare needs supports partnerships between medical homes and families and youth through goal setting and negotiating next steps. In this process, chronic condition management and health surveillance (including adolescent engagement and planning for transition to adult care) occur within an effective patient care relationship, partnering to improve health outcomes and efficiencies of care provision.

INFANCY AND EARLY CHILDHOOD

Nutrition, physical activity, sleep, safety, and emotional, social, and physical growth, along with parental well-being, are critical for all children. For each well-child visit, there are topics that are specific to individual children based on their age, family situation, chronic health condition, or a parental concern, for example, sleep environment to prevent sudden infant death syndrome, activities to lose weight, and fences around swimming pools. Attention should also be focused on the family milieu, including screening for parental depression (especially maternal postpartum depression) and other mental illness, family violence, substance abuse, nutritional inadequacy, or lack of housing. These issues are essential to the care of young children.

Answering parents' questions is the most important priority of the well-child visit. Promoting family-centered care and partnership with parents increases the ability to elicit parent concerns, especially about their child's development, learning, and behavior. It is important to identify children with developmental disorders as early as possible. Developmental surveillance at every visit combined with a structured developmental screening, neuromuscular screening and autism screening at some visits is a way to improve diagnosis, especially for some of

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

2014 Recommendations for Preventive Pediatric Health Care

Bright Futures/American Academy of Pediatrics

Bright Futures. prevention and health promotion for infants, children, adolescents, and their families™

Each child and family is unique; therefore, these Recommendations for Preventive Pediatric Health Care are designed for the care of children who are receiving competent parenting, have no manifestations of any important health problems, and are growing and developing in satisfactory fashion. Additional visits may become necessary if circumstances suggest variations from normal.

Developmental, psychosocial, and chronic disease issues for children and adolescents may require frequent counseling and treatment visits separate from preventive care visits.

These guidelines represent a consensus by the American Academy of Pediatrics (AAP) and Bright Futures. The AAP continues to emphasize the great importance of continuity of care in comprehensive health supervision and the need to avoid fragmentation of care.

Refer to the specific guidance by age as listed in *Bright Futures* guidelines (Hagan JF, Shaw JS, Duncan PM, eds. *Bright Futures Guidelines for Health Supervision of Infants, Children and Adolescents*. 3rd ed. Elk Grove Village, IL: American Academy of Pediatrics; 2008).

The recommendations in this statement do not indicate an exclusive course of treatment or standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

1. If a child comes under care for the first time at any point on the schedule, or if any items are not accomplished at the suggested age, the schedule should be brought up to date at the earliest possible time.
2. A prenatal visit is recommended for parents who are at high risk, for first-time parents, and for those who request a conference. The prenatal visit should include anticipatory guidance, pertinent medical history, and a discussion of benefits of breastfeeding and planned method of feeding, per the 2009 AAP statement "The Prenatal Visit" (http://pediatrics.aappublications.org/content/124/4/1227.full).
3. Every infant should have a newborn evaluation after birth, and breastfeeding should be encouraged (and instruction and support should be offered).
4. Every infant should have an evaluation within 3 to 5 days of birth and within 48 to 72 hours after discharge from the hospital to include evaluation for feeding and jaundice. Breastfeeding infants should receive formal breastfeeding evaluation, and their mothers should receive encouragement and instruction, as recommended in the 2012 AAP statement "Breastfeeding and the Use of Human Milk" (http://pediatrics.aappublications.org/content/129/3/e827.full). Newborn infants discharged less than 48 hours after delivery must be examined within 48 hours of discharge, per the 2010 AAP statement "Hospital Stay for Healthy Term Newborns" (http://pediatrics.aappublications.org/content/125/2/405.full).
5. Screen, per the 2007 AAP statement "Expert Committee Recommendations Regarding the Prevention, Assessment, and Treatment of Child and Adolescent Overweight and Obesity: Summary Report" (http://pediatrics.aappublications.org/content/120/Supplement_4/S164.full).
6. Blood pressure measurement in infants and children with specific risk conditions should be performed at visits before age 3 years.
7. If the patient is uncooperative, rescreen within 6 months, per the 2007 AAP statement "Eye Examination in Infants, Children, and Young Adults by Pediatricians" (http://pediatrics.aappublications.org/content/111/4/902.abstract).
8. All newborns should be screened, per the AAP statement "Year 2007 Position Statement: Principles and Guidelines for Early Hearing Detection and Intervention Programs" (http://pediatrics.aappublications.org/content/120/4/898.full).
9. See 2006 AAP statement "Identifying Infants and Young Children With Developmental Disorders in the Medical Home: An Algorithm for Developmental Surveillance and Screening" (http://pediatrics.aappublications.org/content/118/1/405.full).
10. Screening should occur per the 2007 AAP statement "Identification and Evaluation of Children with Autism Spectrum Disorders" (http://pediatrics.aappublications.org/content/120/5/1183.full).
11. A recommended screening tool is available at http://www.ceasar-boston.org/CRAFFT/index.php.
12. Recommended screening using the Patient Health Questionnaire (PHQ)-2 or other tools available in the GLAD-PC toolkit and at http://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/Mental-Health/Documents/MH_ScreeningChart.pdf.
13. At each visit, age-appropriate physical examination is essential, with infant totally unclothed and older children undressed and suitably draped. See 2011 AAP statement "Use of Chaperones During the Physical Examination of the Pediatric Patient" (http://pediatrics.aappublications.org/content/127/5/991.full).
14. These may be modified, depending on entry point into schedule and individual need.
15. The Recommended Uniform Newborn Screening Panel (http://www.hrsa.gov/advisorycommittees/mchbadvisory/heritabledisorders/recommendedpanel/uniformscreeningpanel.pdf), as determined by The Secretary's Advisory Committee on Heritable Disorders in Newborns and Children, and state newborn screening laws/regulations (http://genes-r-us.uthscsa.edu/sites/genes-r-us/files/nbsdisorders.pdf), establish the criteria for and coverage of newborn screening procedures and programs. Follow-up must be provided, as appropriate, by the pediatrician.
16. Screening for critical congenital heart disease using pulse oximetry should be performed in newborns, after 24 hours of age, before discharge from the hospital, per the 2011 AAP statement "Endorsement of Health and Human Services Recommendation for Pulse Oximetry Screening for Critical Congenital Heart Disease" (http://pediatrics.aappublications.org/content/129/1/190.full).
17. Schedules, per the AAP Committee on Infectious Diseases, are available at: http://aapredbook.aappublications.org/site/resources/izschedules.xhtml. Every visit should be an opportunity to update and complete a child's immunizations.
18. See 2010 AAP statement "Diagnosis and Prevention of Iron Deficiency and Iron Deficiency Anemia in Infants and Young Children (0-3 Years of Age)" (http://pediatrics.aappublications.org/content/126/5/1040.full).
19. For children at risk of lead exposure, see the 2012 CDC Advisory Committee on Childhood Lead Poisoning Prevention statement "Low Level Lead Exposure Harms Children: A Renewed Call for Primary Prevention" (http://www.cdc.gov/nceh/lead/ACCLPP/Final_Document_030712.pdf).
20. Perform risk assessments or screenings as appropriate, based on universal screening requirements for patients with Medicaid or in high prevalence areas.
21. Tuberculosis testing per recommendations of the Committee on Infectious Diseases, published in the current edition of *AAP Red Book: Report of the Committee on Infectious Diseases*. Testing should be performed on recognition of high-risk factors.
22. See AAP-endorsed 2011 guidelines from the National Heart Blood and Lung Institute, "Integrated Guidelines for Cardiovascular Health and Risk Reduction in Children and Adolescents" (http://www.nhlbi.nih.gov/guidelines/cvd_ped/index.htm).
23. Adolescents should be screened for sexually transmitted infections (STIs) per recommendations in the current edition of the *AAP Red Book: Report of the Committee on Infectious Diseases*. Additionally, all adolescents should be screened for HIV according to the AAP statement (http://pediatrics.aappublications.org/content/128/5/1023.full) once between the ages of 16 and 18, making every effort to preserve confidentiality of the adolescent. Those at increased risk of HIV infection, including those who are sexually active, participate in injection drug use, or are being tested for other STIs, should be tested for HIV and reassessed annually.
24. See USPSTF recommendations (http://www.uspreventiveservicestaskforce.org/uspstf/uspscerv.htm). Indications for pelvic examinations prior to age 21 are noted in the 2010 AAP statement "Gynecologic Examination for Adolescents in the Pediatric Office Setting" (http://pediatrics.aappublications.org/content/126/3/583.full).
25. Refer to a dental home, if available. If not available, perform a risk assessment (http://www2.aap.org/oralhealth/docs/RiskAssessmentTool.pdf). If primary water source is deficient in fluoride, consider oral fluoride supplementation. For those at high risk, consider application of fluoride varnish for caries prevention. See 2008 AAP statement "Preventive Oral Health Intervention for Pediatricians" (http://pediatrics.aappublications.org/content/122/6/1387.full) and 2009 AAP statement "Oral Health Risk Assessment Timing and Establishment of the Dental Home" (http://pediatrics.aappublications.org/content/111/5/1113.full).

the more subtle delays or autism spectrum disorders where early intervention is believed to be associated with reduced morbidity.

MIDDLE CHILDHOOD AND ADOLESCENCE

As the child enters school-age years, additional considerations emerge. Attention to developing autonomy requires fostering a clinician–patient relationship separate from the clinician–child-family relationship with increasing needs for privacy and confidentiality as the child ages.

The 6 health behaviors that most significantly impact adolescent and adult morbidity and mortality are inadequate physical activity, poor nutrition, sexuality-related behaviors, substance use and abuse (including tobacco), unintentional injury-related behaviors, and intentional injury-related behaviors. Emotional well-being and early diagnosis and treatment of mental health problems are equally important, with attention to the developmental tasks of adolescence (competence at school and other activities, connection to friends and family, autonomy, empathy, and a sense of self-worth).

OFFICE INTERVENTION FOR BEHAVIORAL AND MENTAL HEALTH ISSUES

One-fifth of primary care encounters with children are for a behavioral or mental health problem, or are sickness visits complicated by a mental health issue. Pediatricians require increased knowledge for diagnosis, treatment, and referral criteria for attention-deficit/hyperactivity disorder (see Chapter 33), depression and other mood disorders (see Chapter 26), anxiety (see Chapter 25), and conduct disorder (see Chapter 29), as well as an understanding of the pharmacology of the frequently prescribed psychotropic medications. Familiarity with available local mental health services and clinicians and knowledge of the types of services indicated are important for effective consultation or referral. Encouragement of behavioral change is also an important responsibility of the clinician. Motivational interviewing provides a structured approach that has been designed to help patients and parents identify the discrepancy between their desire for health and their behavioral choices. It also allows the clinician to use proven strategies that lead to a patient-initiated plan for change.

STRENGTH-BASED APPROACHES AND FRAMEWORK

Questions about school or extracurricular accomplishments or competent personal characteristics should be integrated into the content of the well child visit. Such inquiries set a positive context for the visit, deepen the partnership with the family, acknowledge the child's healthy development, and facilitate discussing social–emotional development with children and their parents. There is a strong relationship between appropriate social–emotional development (e.g., children's strong connection to their family, social friends, and mentors; competence; empathy; and appropriate autonomy) and decreased participation in all the risk behaviors of adolescence (related to drugs, sex, and violence). An organized approach to the identification and encouragement of a child's strengths during health supervision visits provides both the child and parent with an understanding of how to promote healthy achievement of the developmental tasks of childhood and adolescence. Children with special health needs often have a different timetable, but they have an equal need to be encouraged to develop strong family and peer connections, competence in a variety of arenas, ways to do things for others, and appropriate independent decision making.

OFFICE SYSTEM CHANGE FOR QUALITY IMPROVEMENT

Some of the office strategies to improve the preventive services delivered to children and youth include screening schedules and parent handouts, flow sheets, registries, and the use of parent and youth previsit questionnaires. Such tools are available in *The Bright Futures Guidelines Toolkit* and online previsit tools are under construction. These efforts are part of a larger national effort that is built on a coordinated team approach in the office setting and the use of continuous measurement for improvement.

EVIDENCE

Available evidence should be utilized in developing health-promotion and disease-detection recommendations. Revisions to the AAP's *Periodicity Schedule* undergo rigorous evidence assessment; however, many highly valued well-child care activities have not been evaluated for efficacy. Lack of evidence is most often related to absence of study and does not define lack of benefit. Thus the clinical encounter with the well child is also guideline- and recommendation-driven and requires the integration of clinician goals, family needs, and community realities in seeking better health for the child. The rationale for well-child care activities is a balance of evidence from research, clinical practice guidelines, professional recommendations, expert opinion, experience and knowledge of the needs of the patient population in the context of community assets and challenges. Clinical or counseling decisions and recommendations may also be based on legislation (seat belts), on common sense measures not likely to be studied experimentally (lowering water heater temperatures), or on the basis of relational evidence (television watching associated with violent behavior in young children). Most important, sound clinical and counseling decisions are responsive to family needs and desires, and support "patient-centered decision making."

CARING FOR THE CHILD AND YOUTH IN THE CONTEXT OF THE FAMILY AND COMMUNITY

A successful primary care practice for children incorporates families, is family centered, and embraces the concept of the medical home. A medical home is defined by the AAP as primary care that is accessible, continuous, comprehensive, family centered, coordinated, compassionate, and culturally effective. In a medical home, a pediatrician works in partnership with the family and patient to assure that all medical and nonmedical needs of the child are met. Through this partnership, the child healthcare professional helps the family/patient access and coordinate specialty care, educational services, out-of-home care, family support, and other public and private community services that are important to the overall health of the child and family.

Ideally, health promotion activities occur not only in the medical home, but also in partnership with community members and other health and education professionals. This rests on a clear understanding of the important role that the community plays in supporting healthy behaviors among families. Communities where children and families feel safe and valued, and have access to positive activities and relationships, provide the important base that the healthcare professional can build on and refer to for needed services that support health but are outside the realm of the healthcare system or primary care medical home. It is important for the medical home and community agencies to identify mutual resources, communicate well with families and each other, and partner in designing service delivery systems. This interaction is the practice of community pediatrics, whose unique feature is its concern for all of the population: those who remain well but need preventive services, those who have symptoms but do not receive effective care, and those who do seek medical care either in a physician's office or in a hospital.

5.1 Injury Control

Frederick P. Rivara and David C. Grossman

In all high-income countries of the world, and in many low- and middle-income countries, injuries are the most common cause of death during childhood and adolescence beyond the first few months of life and represent 1 of the most important causes of preventable pediatric morbidity and mortality in the United States (see Table 1-2 in Chapter 1 and Fig. 5-2). The identification of risk factors for injuries has led to the development of successful programs for prevention and control. Strategies for injury prevention and control should be pursued

by the pediatrician in the office, emergency department, hospital, and community setting and be done in a multidisciplinary, multifaceted fashion.

INJURY CONTROL (FORMERLY CALLED ACCIDENT PREVENTION)

Injuries have defined risk and protective factors that can be used to define prevention strategies. The term *accidents* implies an event occurring by chance, without pattern or predictability. In fact, most injuries occur under fairly predictable circumstances to high-risk children and families. Most injuries are preventable.

The reduction of morbidity and mortality from injuries can be accomplished not only through primary prevention (averting the event or injury in the first place), but also through secondary and tertiary prevention. The latter 2 approaches include appropriate emergency medical services for injured children; regionalized trauma care for the child with multiple injuries, severe burns, or traumatic brain injury; and specialized pediatric rehabilitation services that attempt to return children to their previous level of functioning.

Injury control also encompasses intentional injuries (assaults and self-inflicted injuries). These injuries are important in adolescents and young adults, and in some populations, they rank first or second as causes of death in these age groups. Many of the same principles of injury control can be applied to these problems; for example, limiting access to firearms may reduce both unintentional shootings and suicides.

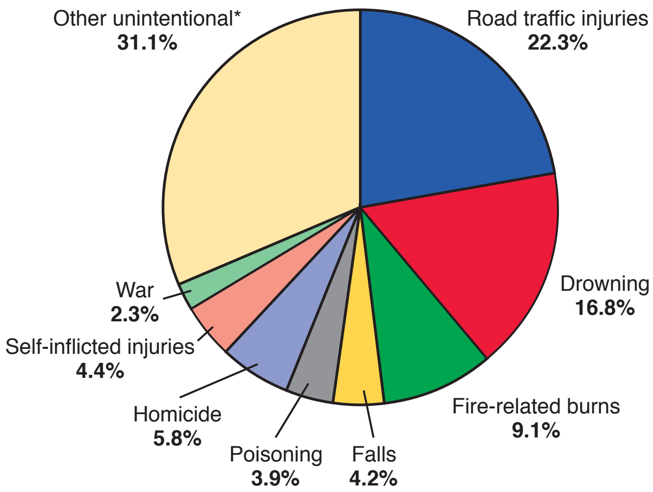

Figure 5-2 Worldwide distribution of global child injury deaths by cause, 0-17 yr of age, 2004. *"Other intentional" includes categories such as smothering, asphyxiation, choking, animal and venomous bites, hypothermia, and hyperthermia, as well as natural disasters. *(From WHO 2008, Global Burden of Disease: 2004 update. www.who.int/violence_injury_prevention/child/injury/wold_report/en/)*

SCOPE OF THE PROBLEM

Mortality

In the United States, injuries cause 41% of deaths among 1-4 yr old children and 3.5 times more deaths than the next leading cause, congenital anomalies. For the rest of childhood and adolescence up to the age of 19 yr, 63% of deaths are a result of injuries, more than all other causes combined. In 2010, injuries caused 13,819 deaths (16 deaths per 100,000) among individuals 19 yr old and younger in the United States (Table 5-1), resulting in more years of potential life lost than any other cause. Unintentional injuries remained the leading cause of death among those <24 yr in 2014 (see Table 1-2).

Motor vehicle injuries lead the list of injury deaths among school-age children and adolescents, and are the second leading cause of injury death for those ages 1-4 yr. In children and adults, motor vehicle **occupant** injuries account for the majority of these deaths. During adolescence, occupant injuries are the leading cause of injury death, accounting for >50% of unintentional trauma mortality in this age group.

Drowning ranks second overall as a cause of unintentional trauma deaths among those ages 1-14 yr, with peaks in the preschool and later teenage years (see Chapter 74). In some areas of the United States, drowning is the leading cause of death from trauma for preschool-age children. The causes of drowning deaths vary with age and geographic area. In young children, bathtub and swimming pool drowning predominate, whereas in older children and adolescents, drowning occurs predominantly in natural bodies of water while the victim is swimming or boating.

Fire and burn deaths account for 8% of all unintentional trauma deaths and 14% in those younger than 5 yr of age (see Chapter 75).

Table 5-1 Injury Deaths in the United States, 2010* [N (Rate per 100,000)]

CAUSE OF DEATH	YOUNGER THAN 1 Yr	1-4 Yr	5-9 Yr	10-14 Yr	15-19 Yr	0-19 Yr

*Injury data from Centers for Disease Control and Prevention: Web-based Injury Statistics Query and Reporting System (WISQARS) (website). National Center for Injury Prevention and Control, Centers for Disease Control and Prevention (producer). Available at http://www.cdc.gov/injury/wisqars/index.html.

All cause data from Centers for Disease Control and Prevention, National Center for Health Statistics. Compressed Mortality File 1999-2010 on CDC WONDER Online Database, released January 2013. Data are compiled from Compressed Mortality File 1999-2010 Series 20 No. 2P, 2013. http://wonder.cdc.gov/cmf-icd10.html

Most of these are a result of house fires; deaths are caused by smoke inhalation and asphyxiation rather than severe burns. Children and the elderly are at greatest risk for these deaths because of difficulty in escaping from burning buildings.

Suffocation accounts for approximately 86% of all unintentional deaths in children younger than 1 yr of age. The majority of these deaths result from choking on food items, such as hot dogs, candy, grapes, and nuts. Nonfood items that can cause choking include undersize infant pacifiers, small balls, and latex balloons. However, some of these deaths may represent misclassification of children dying from sudden infant death syndrome (see Chapter 375).

Homicide is the third leading cause of injury death in children 1-4 yr of age and the second leading cause of injury death in adolescents (15-19 yr old). Homicide in the pediatric age group falls into 2 patterns: infantile and adolescent. Child homicide involves children younger than age 5 yr and represents child abuse (see Chapter 40). The perpetrator is usually a caretaker; death is generally the result of blunt trauma to the head and/or abdomen. The adolescent pattern of homicide involves peers and acquaintances and is caused by firearms in 85% of cases. The majority of these deaths involve handguns. Children between these 2 age groups experience homicides of both types.

Suicide is rare in children younger than age 10 yr; only 1% of all suicides occur in children younger than age 15 yr. The suicide rate increases markedly after the age of 10 yr, with the result that suicide is now the third leading cause of death for 15-19 yr olds. Native American teenagers are at the highest risk, followed by white males; black females have the lowest rate of suicide in this age group. Approximately 40% of teenage suicides involve firearms (see Chapter 27).

In the last decade, there has been a substantial increase in unintentional poisoning deaths among teens and young adults; in 2010 unintentional poisonings were the third leading cause of injury deaths among 15-24 year olds. Many of these were from prescription analgesic and opioid medications.

Nonfatal Injuries

Most childhood injuries do not result in death. Approximately 12% of children and adolescents receive medical care for an injury each year in hospital emergency departments, and at least an equal number are treated in physicians' offices. Of these, 2% require inpatient care and 55% have at least short-term temporary disability as a result of their injuries.

The distribution of these nonfatal injuries is very different from that of fatal trauma (Fig. 5-3). Falls are the leading cause of both emergency department visits and hospitalizations. Bicycle-related trauma is the most common type of sports and recreational injury, accounting for approximately 300,000 emergency department visits annually. Nonfatal injuries, such as anoxic encephalopathy from near-drowning, scarring and disfigurement from burns, and persistent neurologic deficits from head injury, may be associated with severe morbidity, leading to substantial changes in the quality of life for victims and their families.

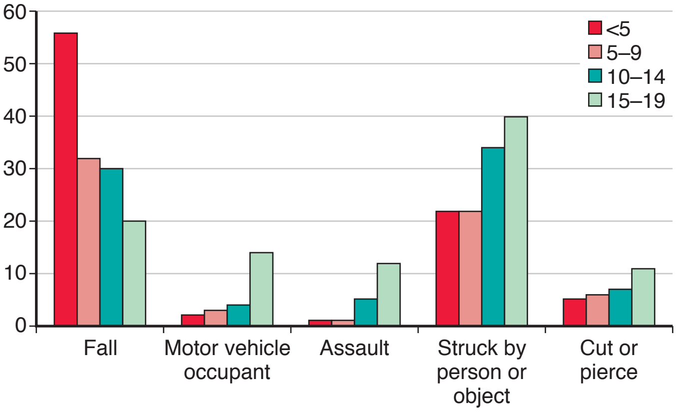

Figure 5-3 Emergency department visits for injuries, 2011. *(Data from NEISS All Injury Program operated by the Consumer Product Safety Commission for numbers of injuries. Bureau of Census for population estimates.)*

Global Child Injuries

Child injuries are a global public health issue and prevention efforts are necessary in low-, middle-, and high-income countries. Between 1990 and 2010 there was a 53% decrease in death rates of people of all ages from communicable, maternal, neonatal, and nutritional disorders whereas injury mortality rates decreased by only 16%. Worldwide, nearly 1 million children and adolescents die from injuries and violence each year, and more than 90% of these deaths are in low- and middle-income countries. As child mortality undergoes an epidemiologic transition because of better control of infectious diseases and malnutrition, injuries have and will increasingly become the leading cause of death for children in the developing world as it now is in all industrialized countries. Drowning is now the 5th most common cause of death for 5-9 yr old children globally, and in some countries, such as Bangladesh, it is the leading cause of death among children beyond the first year of life, with a rate 22 times greater than that in the Americas. An estimated 1 billion people do not currently have access to roads; as industrialization and motorization spreads, the incidence of motor vehicle crashes, injuries, and fatalities will climb. The rate of child injury death in low- and middle-income countries is 3-fold higher than that in high-income countries, and reflects both a higher incidence of many types of injuries as well as a much higher case-fatality ratio in those injured because of a lack of emergency and surgical care. As in high-income countries, prevention of child injuries and consequent morbidity and mortality is feasible with multifaceted approaches, many of which are low cost and of proven effectiveness.

PRINCIPLES OF INJURY CONTROL

Injury prevention once centered on attempts to pinpoint the innate characteristics of a child that result in greater frequency of injury. Most discount the theory of the *accident-prone child.* Although longitudinal studies have demonstrated an association between hyperactivity and impulsivity and increased rates of injury, the sensitivity and specificity of these traits for injury are extremely low. The concept of *accident proneness* is counterproductive in that it shifts attention away from potentially more modifiable factors, such as product design or the environment. It is more appropriate to examine the physical and social environment of children with frequent rates of injury than to try to identify particular personality traits or temperaments, which are difficult to modify. Children at high risk for injury are likely to be relatively poorly supervised, to have disorganized or stressed families, and to live in hazardous environments.

Efforts to control injuries include education or persuasion, changes in product design, and modification of the social and physical environment. Efforts to persuade individuals, particularly parents, to change their behaviors have constituted the greater part of injury control efforts. Speaking with parents specifically about using child car-seat restraints and bicycle helmets, installing smoke detectors, and checking the tap water temperature is likely to be more successful than offering well-meaning but too-general advice about supervising the child closely, being careful, and "childproofing" the home. This information should be geared to the developmental stage of the child and presented in moderate doses in the form of anticipatory guidance at well-child visits. Table 5-2 lists important topics to discuss at each developmental stage.

The most successful injury-prevention strategies generally are those involving changes in product design. These passive interventions protect all individuals in the population, regardless of cooperation or level of skill, and are likely to be more successful than active measures that require repeated behavior change by the parent or child. For some types of injuries, effective passive interventions are not available or feasible; we must rely heavily on attempts to change the behavior of individuals. The most important and effective product changes have been in motor vehicles. Turning down the water heater temperature,

Table 5-2	Injury Prevention Topics for Anticipatory Guidance by the Pediatrician
NEWBORN Car seats Tap water temperature Smoke detectors	
INFANT Car seats Tap water temperature Bath safety	
TODDLER AND PRESCHOOLER Car seats and booster seats Water safety Poison prevention Fall prevention

MIDDLE SCHOOL CHILD Seat belts Safe storage of firearms Water skills training	
HIGH SCHOOL AND OLDER ADOLESCENT Seat belts Alcohol and drug use, especially while driving and swimming Mobile phone use while driving Safe storage of firearms Occupational injuries	

installing smoke detectors, and using child-resistant caps on medicines and household products are other examples of effective product modifications. Many interventions require both active and passive measures. Smoke detectors provide passive protection when fully functional, but behavior change is required to ensure periodic battery changes and proper testing.

Modification of the environment often requires greater changes than individual product modification, but may be very effective in reducing injuries. Safe roadway design, decreased traffic volume and speed limits in neighborhoods, and elimination of guns from households are examples of such interventions. Included in this concept are changes in the social environment through legislation, such as laws mandating child seat restraint and seatbelt use, bicycle helmet use, and graduated driver licensing laws.

Prevention campaigns combining 2 or more of these approaches have been particularly effective in reducing injuries. The classic example is the combination of legislation and education to increase child seat restraint and seatbelt use; other examples are programs to promote bike helmet use among school-aged children and improvements in occupant protection in motor vehicles.

RISK FACTORS FOR CHILDHOOD INJURIES

Major factors associated with an increased risk of injuries to children include age, sex, race and ethnicity, socioeconomic status, rural–urban location, and the environment.

Age

Toddlers are at the greatest risk for burns, drowning, and falling. Poisonings become another risk as these children acquire mobility and exploratory behavior. Young school-age children are at greatest risk for pedestrian injuries, bicycle-related injuries (the most serious of which usually involve motor vehicles), motor vehicle occupant injuries, burns, and drowning. During the teenage years, there is a markedly increased risk from motor vehicle occupant trauma, a continued risk from drowning and burns, and the new risk of intentional trauma. Work-related injuries associated with child labor, especially for 14-16 yr olds, are an additional risk.

Injuries occurring at a particular age represent a window of vulnerability during which a child or an adolescent encounters a new task or hazard that the adolescent may not have the developmental skills to handle successfully. Toddlers do not have the judgment to know that medications can be poisonous or that some houseplants are not to be eaten; they do not understand the hazard presented by a swimming pool or an open second-story window. For young children, parents may inadvertently set up this mismatch between the skills of the child and the demands of the task. Many parents expect young school-age children to walk home from school, the playground, or the local convenience store, tasks for which most children are not developmentally ready. Likewise, the lack of skills and experience to handle many tasks during the teenage years contributes to an increased risk of injuries, particularly motor vehicle injuries. The high rate of motor vehicle crashes among 15-17 yr old teens is caused in part by inexperience, but also appears to reflect their level of development and maturity. Alcohol, other drugs, and mobile phone use substantially add to these limitations.

Age also influences the severity of injury and the risk of long-term disability. Young school-age children have an incompletely developed pelvis. In a motor vehicle crash, the seatbelt does not anchor onto the pelvis, but rides up onto the abdomen, resulting in the risk of serious abdominal injury. Age also interacts with vehicle characteristics in that most children ride in the rear seat, which in the past was equipped only with lap belts and not with lap-shoulder harnesses. Proper restraint for 4-8 yr old children requires the use of booster seats. Children younger than the age of 2 yr have much poorer outcomes from traumatic brain injuries than do older children and adolescents.

Gender

Beginning at 1-2 yr of age and continuing throughout the life span, males have higher rates of fatal injury than females. During childhood, this does not appear to be primarily a result of developmental differences between the sexes, differences in coordination, or differences in muscle strength. Variation in exposure to risk may account for the male predominance in some types of injuries. Although boys in all age groups have higher rates of bicycle-related injuries, adjusting for exposure reduces this excess rate. Boys may have higher rates of injuries because they use bicycles more frequently or for more hours. Sex differences in rates of pedestrian injuries do not appear to be caused by differences in the amount of walking, but rather reflect differences in behavior between young girls and boys. Greater risk-taking behavior, combined with greater frequency of alcohol use, may lead to the disproportionately high rate of motor vehicle crashes among teenage males. The rate of violence related injuries is higher among males because of their risk taking behavior.

Race and Ethnicity

Native Americans have the highest death rate from unintentional injuries. African-American children and adolescents have higher rates of fatal injuries than whites, whereas Asians have lower rates; rates for Hispanic children and adolescents are intermediate between those for African-Americans and those for whites. These discrepancies are even more pronounced for some injuries. The homicide rate for African-Americans age 15-19 yr was 29.6/100,000 in 2010, compared with 6.4/100,000 for American Indians and Alaskan Natives and 4.0/100,000 for whites and 2.0/100,000 for Asians. The suicide rate for Native American youth was 2.2 times the rate for whites and 4.4-fold greater than that for African-Americans. The rate of firearm homicide deaths for African-American youth ages 15-19 is nearly 9-fold higher than that for whites and 21 times that of Asian American youth.

These disparities appear to be primarily related to poverty, the educational status of parents, and the presence of hazardous environments. Homicide rates among African-Americans are nearly equivalent to those among whites, when adjusted for socioeconomic status. It is important to understand racial disparities in injury rates, but

Table 5-3 Recommended Child Restraint Methods

	INFANTS	TODDLERS (1-3)	YOUNG CHILDREN
Recommended age/ weight requirements	*Birth to 1 yr or below weight limit of seat*	*Older than 1 yr and 20-40 lb*	*40-80 lb and under 4′9″ in height; generally between 4 and 8 yr of age*
Type of seat	Infant only or rear-facing convertible	Convertible or forward-facing harness seat	Belt positioning booster seat
Seat position	Rear-facing only. Place in back seat of vehicle	Can be rear-facing until 30 lb if seat allows; generally forward-facing. Place in back seat of vehicle	Forward-facing. Place in back seat of vehicle
Notes	Children should use rear-facing seat until at least 1 yr and at least 20 lb Harness straps should be at or below shoulder level	Harness straps should be at or above shoulder level Most seats require top strap for forward-facing use	Belt positioning booster seats must be used with both lap and shoulder belts Make sure the lap belt fits low and tightly across the lap/upper thigh area and the shoulder belt fits snugly, crossing the chest and shoulder to avoid abdominal injuries

Data from http://www.safercar.gov/parents/CarSeats.htm.

inappropriate to ascribe the etiology of these differences to race or ethnicity.

Socioeconomic Status

Poverty is one of the most important risk factors for childhood injury. Mortality from fires, motor vehicle crashes, and drowning is 2-4 times higher in poor children. Death rates among both African-Americans and whites have an inverse relationship to income level: the higher the income level, the lower the death rate. Native Americans have especially high rates. Other factors are single-parent families, teenage mothers, multiple care providers, family stress, and multiple siblings; these are primarily a function of poverty rather than independent risk factors.

Rural–Urban Location

Injury rates are generally higher in rural than in urban areas. Homicide rates are higher in urban areas, as is violent crime in general. Case fatality from injury is generally twice as high in rural areas than in urban areas, reflecting both the increased severity of some injuries (such as motor vehicle crashes occurring at higher speeds) and poorer access to emergency medical services and definitive trauma care in rural areas. Some injuries are unique to rural areas, such as agricultural injuries to children and adolescents.

Environment

Poverty increases the risk of injury to children, at least in part through its effect on the environment. Children who are poor are at increased risk for injury because they are exposed to more hazards in their living environments. They may live in poor housing, which is more likely to be dilapidated and less likely to be protected by smoke detectors. The roads in their neighborhoods are more likely to be major thoroughfares. Their neighborhoods are more likely to experience higher levels of violence, and they are more likely to be victims of assault than are children and adolescents living in the suburbs. The focus on the environment is also important because it directs attention away from relatively immutable factors, such as family dynamics, poverty, and race, and directs efforts toward factors that can be changed through interventions.

MECHANISMS OF INJURY

Motor Vehicle Injuries

Motor vehicle injuries are the leading cause of serious and fatal injuries for children and adolescents. Large and sustained reductions in motor vehicle crash injuries can be accomplished by identifiable interventions.

Occupants

Injuries to passenger vehicle occupants are the predominant cause of motor vehicle deaths among children and adolescents. The peak injury and death rate for both males and females in the pediatric age group occurs between 15 and 19 yr of age (see Table 5-1). Proper restraint use in vehicles is the single most effective method for preventing serious or fatal injury. Table 5-3 shows the recommended restraints at different ages. Figure 5-4 provides examples of car safety seats.

Much attention has been given to child occupants younger than 8 yr of age. Use of child restraint devices, infant car seats, and booster seats can be expected to reduce fatalities by 71% and the risk of serious injuries by 67% in this age group. All 50 states and the District of Columbia have laws mandating their use, although the upper age limit for booster seat requirements varies by state. Physician reinforcement of the positive benefits of child seat restraints has been successful in improving parent acceptance. Pediatricians should point out to parents that toddlers who normally ride restrained behave better during car trips than children who ride unrestrained.

A detailed guide and list of acceptable devices is available from the AAP (http://www.healthychildren.org/english/safety-prevention/on-the-go/pages/car-safety-seats-information-for-families.aspx) and the National Highway Traffic Safety Administration (http://www.safecar.gov/parents/carseats.htm). Children weighing < 20 lb may use an infant seat or be placed in a convertible infant-toddler child-restraint device. Infants and toddlers younger than 1 to 2 yr or if less than manufacturer's weight limit should be placed in the rear seat facing backward; older toddlers and young children can be placed in the rear seat in a forward-facing child harness seat until it is outgrown. Emphasis must be placed on the correct use of these seats, including placing the seat in the right direction, routing the belt properly, and ensuring that the child is buckled into the seat correctly. Government regulations have made the fit between car seats and the car easier, quicker, and less prone to error. *Children younger than age 13 yr should never sit in the front seat. Inflating airbags can be lethal to infants in rear-facing seats and to small children in the front passenger seat.*

Older children are often not adequately restrained. Many children ride in the rear seat restrained with lap belts only. Booster seats have been shown to decrease the risk of injury by 59%, and should be used by children who are between 40 lb (≈4 yr of age) and 80 lb, are <8 yr of age, and are <4 ft 9 in (145 cm) tall. Many states have extended their car seat laws to include children of booster seat age as well. Shoulder straps placed behind the child or under the arm do not provide adequate crash protection and may increase the risk of serious injury. The use of lap belts alone has been associated an increased risk of seatbelt-related injuries, especially fractures of the lumbar spine and hollow-viscous injuries of the abdomen. These flexion-distraction injuries of the spine are usually accompanied by injuries to the abdominal organs.

The rear seat is clearly much safer than the front seat for both children and adults. One study of children younger than the age of 15 yr found that the risk of injury in a crash was 70% lower for children in the rear seat compared with those sitting in the front seat. Frontal

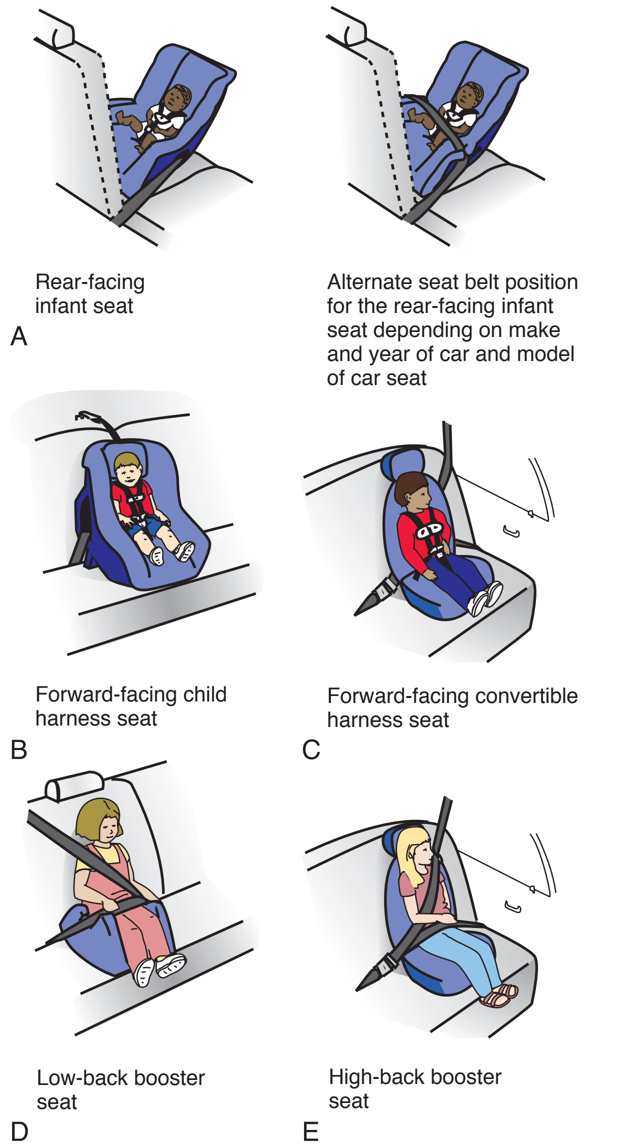

Figure 5-4 Car safety seats. **A,** Rear-facing infant seat. **B,** Forward-facing child harness seat. **C,** Forward-facing convertible harness seat. **D,** Low-back booster seat. **E,** High-back booster seat. *(From Ebel BE, Grossman DC: Crash proof kids? An overview of current motor vehicle child occupant safety strategies, Curr Probl Pediatr Adolesc Health Care 33:33–64, 2003. Source: NHTSA.)*

airbags appear to offer little protection to children in crashes and also present a risk of serious or fatal injury from the airbag itself. Side airbags also pose a risk for children who are in the front seat and are leaning against the door at the time of a crash. The safest place for children is in the rear middle seat, properly restrained for their age and size. Educational and legislative interventions to increase the number of children traveling in the rear seat have been successful.

Transportation of **premature infants** presents special problems. The possibility of oxygen desaturation, sometimes associated with bradycardia, among premature infants while in child seat restraints has led the AAP to recommend an observed trial of infants born at <37 wk of gestational age in the seat before discharge and the use of oxygen or alternative restraints for infants who experience desaturation or bradycardia, such as seats that can be reclined and used as a car bed. Car seats should only be used for travel and not as a general use infant seat around the home.

Children riding in the rear bed of pickup trucks are at special risk for injury because of the possibility of ejection from the truck and resultant serious head injury.

Teenage Drivers

Drivers 15-17 yr of age have more than twice the rate of collisions compared with motorists 18 yr of age and older. Formal driver education courses for young drivers appear to be ineffective as a primary means of decreasing the number of collisions, and in fact may increase risk by allowing younger teens to drive. The risk of serious injury and mortality is directly related to the speed at the time of the crash and inversely related to the size of the vehicle. Small, fast cars greatly increase the risk of a fatal outcome in the event of a crash.

The number of passengers traveling with teen drivers influences the risk of a crash. The risk of death for 17 yr old drivers is 50% greater when driving with 1 passenger compared with driving alone; this risk is 2.6-fold higher with 2 passengers and 3-fold higher with 3 or more passengers. The risk is also increased if the driver is male and the passengers are younger than age 30 yr.

Teens driving at night are overrepresented in crashes and fatal crashes, with nighttime crashes accounting for >33% of teen motor vehicle fatalities. Almost 50% of fatal crashes involving drivers younger than age 18 yr occur in the 4 hr before or after midnight. Teens are 5-10 times more likely to be in a fatal crash while driving at night compared with driving during the day. The difficulty of driving at night combined with the inexperience of teen drivers appears to be a deadly combination.

Another risk factor for motor vehicle crashes for people of all ages, including teens, is distracted driving from the use of mobile devices for texting or talking. In 2011, ⅓ of high school students reported they had texted or emailed while driving in the last 30 days. Dialing on a cell phone increases the risk of a crash nearly 3-fold, and texting may increase the risk as much as 6-fold. Although 44 states have banned text messaging for all drivers, the effect of state laws on prohibiting such behavior well driving is unknown. Parents should set limits on the use of these devices by their teens; technological interventions that can block cell phone signals in a moving vehicle may also be available.

Graduated licensing laws (GLLs) consist of a series of steps over a designated period before a teen can get full, unrestricted driving privileges. In a 3-stage graduated license, the student driver must first pass vision and knowledge-based tests. This is followed by obtaining a learner's permit and once a specific age has been achieved and driving skills advanced, the student driver is eligible to take the driving test. Once given the provisional license, the new driver will have a specified time to do low-risk driving. GLLs usually place initial restrictions on the number of passengers (especially teenaged) allowed in the vehicle and restrict driving during nighttime. There is a decrease in the number of crashes of 10-30% among the youngest drivers in states with a GLL system. The characteristics of GLLs vary substantially across states.

Alcohol use is a major cause of motor vehicle trauma among adolescents. The combination of inexperience in driving and inexperience with alcohol is particularly dangerous. Approximately 20% of all deaths from motor vehicle crashes in this age group are the result of alcohol intoxication, with impairment of driving seen at blood alcohol concentrations as low as 0.05 g/dL. Approximately 30% of adolescents report riding with a driver who had been drinking and approximately 10% report driving after drinking. All states have adopted a zero tolerance policy, which defines any measurable alcohol content as legal intoxication, to adolescent drinking while driving. All adolescent motor vehicle injury victims should have their blood alcohol concentration measured in the emergency department and be screened for high-risk alcohol use with a validated screening test (such as the CRAFFT or Alcohol Use Disorders Identification Test [AUDIT] screening tools) to identify those with alcohol abuse problems (see Chapter 114.1). Individuals who have evidence of alcohol abuse should not leave the emergency department or hospital without plans for appropriate alcohol abuse treatment. Interventions for problem drinking can be effective in decreasing the risk of subsequent motor vehicle crashes. Even brief interventions in the emergency department using motivational interviewing can be successful in decreasing adolescent problem drinking.

Another cause of impaired driving is marijuana use. In 2011, nearly one-quarter of high school students reported using marijuana in the prior 30 days. Marijuana use doubles the risk of a crash; as with alcohol,

this effect may be more pronounced with less experienced drivers. As of this writing, two states (Washington and Colorado) have legalized the sale of marijuana for adults; the effects of this on adolescent injury remains to be determined.

All-Terrain Vehicles. All-terrain vehicles (ATVs) in many parts of the country are an important cause of injuries to children and adolescents. These vehicles can attain high speeds and are prone to rollover because of their high center of gravity. Orthopedic and head injuries are the most common serious injuries seen among children involved in ATV crashes. Helmets can significantly decrease the risk and severity of head injuries among ATV riders, but current use is very low. Voluntary industry efforts to decrease the risk of injuries appear to have had little effect in making ATVs safer. The AAP recommends that children younger than 16 yr of age should not ride on ATVs.

Bicycle Injuries. Each year in the United States, approximately 300,000 children and adolescents are treated in emergency departments for bicycle-related injuries, making this one of the most common reasons that children with trauma visit emergency departments. The majority of severe and fatal bicycle injuries involve head trauma. A logical step in the prevention of these head injuries is the use of helmets. Helmets are very effective, reducing the risk of all head injury by 85% and the risk of traumatic brain injury by 88%. Helmets also reduce injuries to the mid and upper face by as much as 65%. Pediatricians can be effective advocates for the use of bicycle helmets and should incorporate this advice into their anticipatory guidance schedules for parents and children. Appropriate helmets are those with a firm polystyrene liner that fit properly on the child's head. Parents should avoid buying a larger helmet to give the child "growing room."

Promotion of helmet use can and should be extended beyond the pediatrician's office. Community education programs spearheaded by coalitions of physicians, educators, bicycle clubs, and community service organizations have been successful in promoting the use of bicycle helmets to children across the socioeconomic spectrum, resulting in helmet use rates of 60% or more with a concomitant reduction in the number of head injuries. Passage of bicycle helmet laws also leads to increased helmet use.

Consideration should also be given to other types of preventive activities, although the evidence supporting their effectiveness is limited. Bicycle paths are a logical method for separating bicycles and motor vehicles.

Pedestrian Injuries. Pedestrian injuries are an important of traumatic death for children and adolescents in the United States and in most high-income countries. In low-income countries, a much higher proportion of motor vehicle fatalities are pedestrians, especially among 5-14 year olds. Although case fatality rates are <5%, serious nonfatal injuries constitute a much larger problem, resulting in 60,000 emergency department visits annually for children and adolescents. Pedestrian injuries are the most important cause of traumatic coma in children and a frequent cause of serious lower extremity fractures, particularly in school-age children.

Most injuries occur during the day, with a peak in the after-school period. Improved lighting or reflective clothing would be expected to prevent few injuries. Surprisingly, approximately 30% of pedestrian injuries occur while the individual is in a marked crosswalk, perhaps reflecting a false sense of security and decreased vigilance in these areas. The risk of pedestrian injury is greater in neighborhoods with high traffic volumes, speeds greater than ≈25 mph, absence of play space adjacent to the home, household crowding, and low socioeconomic status.

One important risk factor for childhood pedestrian injuries is the developmental level of the child. Children < 5 yr are at risk for being run over in the driveway. Few children < 9 or 10 yr of age have the developmental skills to successfully negotiate traffic 100% of the time. Young children have poor ability to judge the distance and speed of traffic and are easily distracted by playmates or other factors in the environment. Many parents are not aware of this potential mismatch between the abilities of the young school-age child and the skills needed to cross streets safely. The use of mobile phones and devices has become increasingly common while walking, and can increase the risk of being struck by a motor vehicle.

Prevention of pedestrian injuries is difficult, but should consist of a multifaceted approach. Education of the child in pedestrian safety should be initiated at an early age by the parents and continue into the school-age years. Younger children should be taught never to cross streets when alone; older children should be taught (and practice how) to negotiate quiet streets with little traffic. Major streets should not be crossed alone until the child is at least 10 yr of age or older and has been observed to follow safe practices.

Legislation and police enforcement are important components of any campaign to reduce pedestrian injuries. Right-turn-on-red laws increase the hazard to pedestrians. In many cities, few drivers stop for pedestrians in crosswalks, a special hazard for young children. Engineering changes in roadway design are extremely important as passive prevention measures. Most important are measures to slow the speed of traffic and to route traffic away from schools and residential areas; these efforts are endorsed by parents and can decrease the risk of injuries and death by 10-35%. Other modifications include networks of 1-way streets, proper placement of transit or school bus stops, sidewalks in urban and suburban areas, edge stripping in rural areas to delineate the edge of the road, and curb parking regulations. Comprehensive traffic "calming" schemes using these strategies have been very successful in reducing child pedestrian injuries in Sweden, the Netherlands, Germany, and increasingly, the United States.

Ski- and Snowboard-Related Head Injuries. The increasing use of helmets in snow sports, such as skiing and snowboarding, is encouraging .since head injuries are the most common cause of death in these sports, and helmets reduce the risk of head injury by 50% or more. Use of helmets does not result in skiers or snow boarders taking more risks and should be encouraged in all snow sports.

Fire- and Burn-Related Injuries. See Chapter 75.

Poisoning. See Chapter 63.

Drowning. See Chapter 74.

Traumatic Brain Injury. See Chapter 68.

Firearm Injuries. Injuries to children and adolescents involving firearms occur in 3 different situations: unintentional injury, suicide attempt, and assault. The injury induced may be fatal or may result in permanent sequelae.

Unintentional firearm injuries and deaths have continued to decrease and accounted for 134 deaths in 2010, representing only a very small fraction of all firearm injuries among children and adolescents. The majority of these deaths occur to teens during hunting or recreational activities. **Suicide** is the third most common cause of death from all causes in both males and females ages 10-19 yr. During the 1950s to 1970, suicide rates for children and adolescents more than doubled; firearm suicide rates peaked in 1994 and decreased by 59% from this peak by 2010. The difference in the rate of suicide death between males and females is related to the differences in method used during attempts. Women die less often in suicide attempts, partly because they use less-lethal means (mainly drugs) and perhaps have a lower degree of intent. The use of firearms in a suicidal act usually converts an attempt into a fatality.

Homicides are second only to motor vehicle crashes among causes of death in teenagers older than 15 yr. In 2010, 1,832 adolescents age 15-19 yr were homicide victims; African American teenagers accounted for 52% of the total, making homicides the most common cause of death among African-American teenagers. Hispanic teenagers accounted for nearly 17% of the homicide deaths in this age group. In 2010, 85% of homicides among teenage males involved firearms, the majority of which are handguns.

In the United States, approximately 34% of households owned guns in 2012. Handguns account for approximately 30% of the firearms in use today, yet they are involved in 80% of criminal and other firearm misuse. Home ownership of guns increases the risk of adolescent suicide 3- to 10-fold and the risk of adolescent homicide up to 4-fold. In homes with guns, the risk to the occupants is far greater than the chance that the gun will be used against an intruder; for every death

occurring in self-defense, there may be 1.3 unintentional deaths, 4.6 homicides, and 37 suicides.

Of all firearms, handguns pose the greatest risk to children and adolescents. Access to handguns by adolescents is surprisingly common and is not restricted to those involved in gang or criminal activity. Stricter approaches to reduce youth access to handguns, rather than all firearms, would appear to be the most appropriate focus of efforts to reduce shooting injuries in children and adolescents.

Locking and unloading guns as well as storing ammunition locked in a different location substantially reduces the risk of a suicide or unintentional firearm injury among youth by up to 73%. Because up to 30% of handgun-owning households have at least 1 firearm stored unsafely, 1 potential approach to reducing these injuries could focus on improving household firearm storage practices where children and youth reside or visit. The evidence regarding the effectiveness of office-based counseling to influence firearm storage practice is mixed.

Adolescents with mental health conditions and alcoholism are at particularly high risk for firearm injury. In the absence of conclusive evidence, physicians should continue to work with families to eliminate access to guns in these households.

Falls. Falls are the leading cause of nonfatal injury in children and adolescents. Altogether, there were 2.9 million falls that led to emergency department visits in 2011 for children and adolescents; approximately 1.7% of these visits led to a hospitalization. There have been relatively few in-depth analytic studies of falls, except in particular circumstances, such as playground injuries. Strategies to prevent falls depend on the environmental circumstances and social context in which they occur. Window falls have been successfully prevented with the use of devices that prevent egress, and injuries from playground falls can be mitigated through the use of proper surfacing, such as woodchips or other soft, energy-absorbing materials. Alcohol may also contribute to falls among teenagers, and these injuries can be reduced by general strategies to reduce teen alcohol use.

Violent Behavior and Aggression. Although the current rates of homicide are much lower than they were at their peak in the late 1980s and early 1990s, the problem of violence and assault is still large. The origins of adult and teen violence occur during childhood. Adults who commit violent acts usually have a history of violent behavior during childhood or adolescence. Longitudinal studies following groups of individuals from birth have found that aggression occurs among infants and that most children learn to control this aggression early in childhood. Children who later become violent adolescents and adults do not learn to control this aggressive behavior.

The most successful interventions for violence target young children and their families. These include home visits by nurses and paraprofessionals beginning in the prenatal period and continuing for the first few years of life to provide support and guidance to parents, especially parents without other resources. Enrollment in early childhood education programs (e.g. Head Start) starting at age 3 yr has been shown to be effective in improving school success, keeping children in school, and decreasing the chance that the child will be a delinquent adolescent. School-based interventions, including curricula to increase the social skills of children and improve the parenting skills of caregivers, have long-term effects on violence and risk-taking behavior. Early identification of behavior problems by primary care pediatricians can best be accomplished through the routine use of formal screening tools. Interventions in adolescence, such as family therapy, multisystemic therapy, and therapeutic foster care, can decrease problem behavior and a subsequent decline into delinquency and violence.

Psychosocial Consequences of Injuries

Many children and their parents have substantial psychosocial sequelae from trauma. Studies in adults indicate that 10-40% of hospitalized injured patients will have posttraumatic stress disorder (PTSD; see Chapter 25). Among injured children involved in motor vehicle crashes, 90% of families will have symptoms of acute stress disorder after the crash, although the diagnosis of acute stress disorder is not predictive of later PTSD. Standardized questionnaires that collect data from the child, the parents, and the medical record at the time of initial injury can serve as useful screening tests for later development of PTSD. Early mental health intervention, with close follow-up, is important for the treatment of PTSD and for minimizing its effect on the child and family.

Growth, Development, and Behavior

PART II

Chapter 6
Overview and Assessment of Variability

Susan Feigelman

The field of pediatrics is dedicated to optimizing the growth and development of each child. Pediatricians require knowledge of normal growth, development, and behavior in order to effectively monitor children's progress, identify delays or abnormalities in development, obtain needed services, and counsel parents and caretakers. To alter factors that increase or decrease risk, pediatricians need to understand how biologic and social forces interact within the parent-child relationship, within the family, and between the family and the larger society. Growth is an indicator of overall well-being, status of chronic disease, and interpersonal and psychologic stress. By monitoring children and families over time, pediatricians are uniquely situated to observe the interrelationships between physical growth and cognitive, motor, and emotional development. Observation is enhanced by familiarity with developmental theory and understanding of developmental models which describe normal patterns of behavior and provide guidance for prevention of behavior problems.

BIOPSYCHOSOCIAL MODEL AND ECOBIODEVELOPMENTAL FRAMEWORK: MODELS OF DEVELOPMENT

The medical model presumes that a patient presents with signs and symptoms and a physician focuses on diagnosing and treating diseases of the body. This model neglects the psychologic aspect of a person who exists in the larger realm of the family and society. In the **biopsychosocial model**, higher-level systems are simultaneously considered with the lower-level systems that make up the person and the person's environment (Fig. 6-1). A patient's symptoms are examined and explained in the context of the patient's existence. This basic model can be used to understand health and both acute and chronic disease.

With the advances in neurology, genomics including epigenetics, molecular biology and the social sciences, a more accurate model, the **ecobiodevelopmental framework** has emerged. This framework emphasizes how the ecology of childhood (social and physical environments) interacts with biologic processes to determine outcomes and life trajectories. Early influences, particularly those producing toxic levels of stress, affect the individual through modification of gene expression, without change in DNA sequencing. These **epigenetic changes**, such as DNA methylation and histone acetylation, are a result of environmental insults. Stress responses may produce alterations in brain structure and function, leading to disruption of later coping mechanisms. These changes will produce long-lasting effects on the health and well-being of the individual and may be passed on to future generations (Fig. 6-2).

Critical to learning and remembering (and therefore development) is **neuronal plasticity**, which permits the central nervous system to reorganize neuronal networks in response to environmental stimulation, both positive and negative. An overproduction of neuronal precursors eventually leads to about 100 billion neurons in the adult brain. Each neuron develops on average 15,000 synapses by 3 yr of age. Synapses in frequently used pathways are preserved, whereas less-used ones atrophy, through neuronal "pruning." Changes in the strength and number of synapses and reorganization of neuronal circuits also play important roles in brain plasticity. Increases or decreases in synaptic activity result in persistent increases or decreases in synaptic strength. Thus experience (**environment**) has a direct effect on the physical and therefore functional properties of the brain (**genetics**). Children with different talents and temperaments (already a combination of genetics and environment) further elicit different stimuli from their (differing) environments.

Periods of behavioral development generally correlate with periods of great changes in synaptic numbers in relevant areas of the brain. Accordingly, sensory deprivation during the time when synaptic changes should be occurring has profound effects. The effects of strabismus leading to amblyopia in 1 eye may occur quickly during early childhood; likewise, patching the eye with good vision to reverse amblyopia in the other eye is less effective in late childhood (see Chapter 621). Early experience is particularly important because learning proceeds more efficiently along established synaptic pathways. Traumatic experiences also create enduring alterations in the neurotransmitter and endocrine systems that mediate the stress response, with effects noted later in life. Positive and negative experiences do not determine the total outcome, but shift the probabilities by influencing the child's ability to respond adaptively to future stimuli. The plasticity of the brain continues into adolescence, with further development of the prefrontal cortex, which is important in decision-making, future planning, and emotional control; neurogenesis persists in adulthood in certain areas of the brain, including the subventricular zone of the lateral ventricles and in portions of the hippocampus.

Biologic Influences

Biologic influences on development include genetics, in utero exposure to teratogens, the long-term negative effects of low birthweight (neonatal morbidities plus increased rates of obesity, coronary heart disease, stroke, hypertension, and type 2 diabetes), postnatal illnesses, exposure to hazardous substances, and maturation. Adoption and twin studies consistently show that heredity accounts for approximately 40% of the variance in IQ and in other personality traits, such as sociability and desire for novelty, whereas shared environment accounts for another 50%. The negative effects on development of prenatal exposure to teratogens, such as mercury and alcohol, and of postnatal insults, such as meningitis and traumatic brain injury, have been extensively studied (see Chapters 96 and 99). Any chronic illness can affect growth and development, either directly or through changes in nutrition, parenting, or peer interactions.

The age at which children walk independently is similar around the world, despite great variability in child-rearing practices. The attainment of other skills, such as the use of complex sentences, is less tightly bound to a maturational schedule. Maturational changes also generate behavioral challenges at predictable times. Decrements in growth rate and sleep requirements around 2 yr of age often generate concern about poor appetite and refusal to nap. Although it is possible to accelerate many developmental milestones (toilet training a 12 mo old or teaching a 3 yr old to read), the long-term benefits of such precocious accomplishments are questionable.

In addition to physical changes in size, body proportions, and strength, maturation brings about hormonal changes. Sexual differentiation, both somatic and neurologic, begins in utero. Both stress and reproductive hormones affect brain development as well as behavior throughout development.

Temperament describes the stable, early-appearing individual variations in behavioral dimensions, including emotionality (crying, laughing, sulking), activity level, attention, sociability, and persistence. The classic theory proposes 9 dimensions of temperament (Table 6-1). These characteristics lead to 3 common constellations: (1) the easy, highly adaptable child, who has regular biologic cycles; (2) the difficult child, who withdraws from new stimuli and is easily frustrated; and (3) the slow-to-warm-up child, who needs extra time to adapt to new circumstances. Various combinations of these clusters also occur. Temperament has long been described as biologic or "inherited." Monozygotic twins are rated by their parents as temperamentally similar more often than are dizygotic twins. Estimates of heritability suggest that genetic differences account for approximately 20-60% of the variability of temperament within a population. The remainder of the variance is attributed to the child's environment. Maternal prenatal stress and anxiety is associated with child temperament, possibly through stress hormones. However, certain polymorphisms of specific genes moderate the influence of maternal stress on infant temperament (specifically irritability) illustrating the interplay between genes and environment. Longitudinal twin studies of adult personality indicate that changes in personality over time largely result from non-shared environmental influences, whereas stability of temperament appears to result from genetic factors.

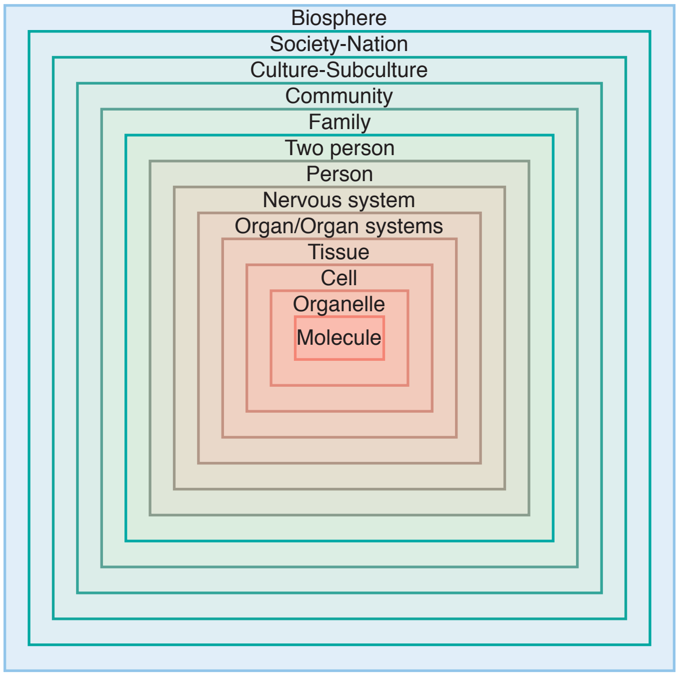

Figure 6-1 Continuum and hierarchy of natural systems in the biopsychosocial model. *(From Engel GL: The clinical application of the biopsychosocial model,* Am J Psychiatry *137:535–544, 1980.)*

The concept of temperament can help parents understand and accept the characteristics of their children without feeling responsible for having caused them. Children who have difficulty adjusting to change may have behavior problems when a new baby arrives or at the time of school entry. In addition, pointing out the child's temperament may allow for adjustment in parenting styles. Behavioral and emotional problems may develop when the temperamental characteristics of children and parents are in conflict.

Psychologic Influences: Attachment and Contingency

The influence of the child-rearing environment dominates most current models of development. Infants in hospitals and orphanages, devoid of opportunities for attachment, have severe developmental deficits. **Attachment** refers to a biologically determined tendency of a young child to seek proximity to the parent during times of stress and also to the relationship that allows securely attached children to use

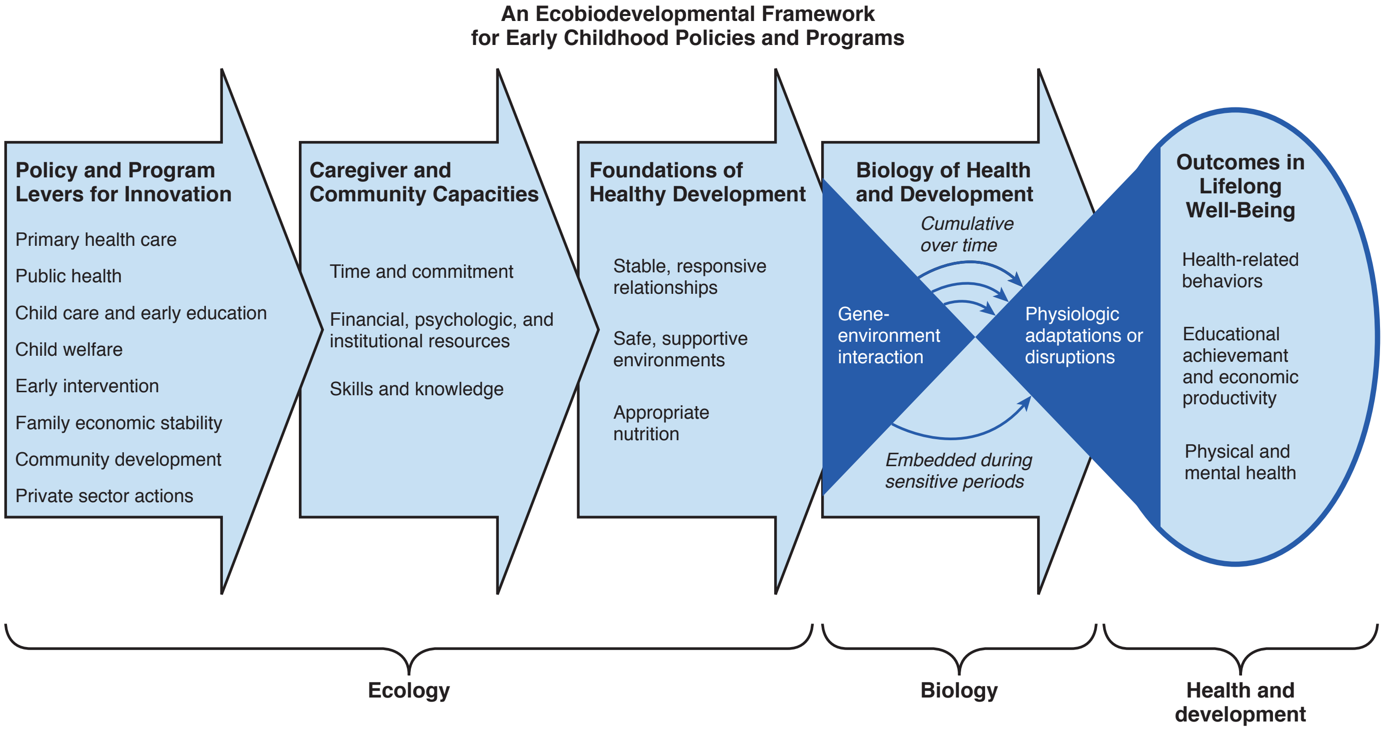

Figure 6-2 An ecobiodevelopmental framework for early childhood policies and programs. *(Adapted from Center on the Developing Child at Harvard University. The foundations of lifelong health are built in early childhood. Available at:* http://developingchild.harvard.edu/index.php/resources/reports_and_working_papers/foundations-of-lifelong-health/ *and published in* Pediatrics: *Shonkoff JP, Garner AS, The Committee on Psychosocial Aspects of Child and Family Health, Committee on Early Childhood, Adoption, and Dependent Care, and Section of Developmental and Behavioral Pediatrics: The lifelong effects of early childhood adversity and toxic stress.* Pediatrics *129(1):e232–e246, 2012.)*

Table 6-1 Temperamental Characteristics: Descriptions and Examples

CHARACTERISTIC	DESCRIPTION	EXAMPLES*
Activity level	Amount of gross motor movement	"She's constantly on the move." "He would rather sit still than run around."
Rhythmicity	Regularity of biologic cycles	"He's never hungry at the same time each day." "You could set a watch by her nap."
Approach and withdrawal	Initial response to new stimuli	"She rejects every new food at first." "He sleeps well in any place."
Adaptability	Ease of adaptation to novel stimulus	"Changes upset him." "She adjusts to new people quickly."
Threshold of responsiveness	Intensity of stimuli needed to evoke a response (e.g., touch, sound, light)	"He notices all the lumps in his food and objects to them." "She will eat anything, wear anything, do anything."
Intensity of reaction	Energy level of response	"She shouts when she is happy and wails when she is sad." "He never cries much."
Quality of mood	Usual disposition (e.g., pleasant, glum)	"He does not laugh much." "It seems like she is always happy."
Distractibility	How easily diverted from ongoing activity	"She is distracted at mealtime when other children are nearby." "He doesn't even hear me when he is playing."
Attention span and persistence	How long a child pays attention and sticks with difficult tasks	"He goes from toy to toy every minute." "She will keep at a puzzle until she has mastered it."

*Typical statements of parents, reflecting the range for each characteristic from very little to very much.
Based on Chess S, Thomas A: Temperament in clinical practice, *New York, 1986, Guilford.*

their parents to reestablish a sense of well-being after a stressful experience. Insecure attachment may be predictive of later behavioral and learning problems.

At all stages of development, children progress optimally when they have adult caregivers who pay attention to their verbal and nonverbal cues and respond accordingly. In early infancy, such contingent responsiveness to signs of overarousal or underarousal helps maintain infants in a state of quiet alertness and fosters autonomic self-regulation. **Contingent responses** (reinforcement depending on the behavior of the other) to nonverbal gestures create the groundwork for the shared attention and reciprocity that are critical for later language and social development. Children learn best when new challenges are just slightly harder than what they have already mastered, a degree of difficulty dubbed the "zone of proximal development." Psychologic forces, such as attention problems (see Chapter 33) or mood disorders (see Chapter 26), will have profound effects on many aspects of an older child's life.

Social Factors: Family Systems and the Ecologic Model

Contemporary models of child development recognize the critical importance of influences outside of the mother–child dyad. Fathers play critical roles, both in their direct relationships with their children and in supporting mothers. As traditional nuclear families become less dominant, the influence of other family members (grandparents, foster and adoptive parents, same-sex partners) becomes increasingly important. Children are increasingly raised by unrelated caregivers while parents work or while they are in foster care.

Families function as systems, with internal and external boundaries, subsystems, roles, and rules for interaction. In families with rigidly defined parental subsystems, children may be denied any decision-making, exacerbating rebelliousness. In families with poorly defined parent–child boundaries, children may be required to take on responsibilities beyond their years, or may be recruited to play a spousal role.

Family systems theory recognizes that individuals within systems adopt implicit roles. One child may be the troublemaker, whereas another is the negotiator and another is quiet. Birth order may have profound effects on personality development, through its influence on family roles and patterns of interaction. Families are dynamic. Changes in one person's behavior affect every other member of the system; roles shift until a new equilibrium is found. The birth of a new child, attainment of developmental milestones such as independent walking, the onset of nighttime fears, and the death of a grandparent are all changes that require renegotiation of roles within the family and have the potential for healthy adaptation or dysfunction.

The family system, in turn, functions within the larger systems of extended family, subculture, culture, and society. Bronfenbrenner's ecologic model depicts these relationships as concentric circles, with the parent–child dyad at the center (with associated risks and protective factors) and the larger society at the periphery. Changes at any level are reflected in the levels above and below. The shift from an industrial economy to one based on service and information is an obvious example of societal change with profound effects on families and children.

Unifying Concepts: The Transactional Model, Risk, and Resilience

The **transactional model** proposes that a child's status at any point in time is a function of the interaction between biologic and social influences. The influences are bidirectional: Biologic factors, such as temperament and health status, both affect the child-rearing environment and are affected by it. A premature infant may cry little and sleep for long periods; the infant's depressed parent may welcome this good behavior, setting up a cycle that leads to poor nutrition and inadequate growth. The child's failure to thrive may reinforce the parent's sense of failure as a parent. At a later stage, impulsivity and inattention associated with early, prolonged undernutrition may lead to aggressive behavior. The cause of the aggression in this case is not the prematurity, the undernutrition, or the maternal depression, but the interaction of all these factors (Fig. 6-3). Conversely, children with biologic risk factors may nevertheless do well developmentally if the child-rearing environment is supportive. Premature infants with electroencephalographic evidence of neurologic immaturity may be at increased risk for cognitive delay. This risk may only be realized when the quality of parent–child interaction is poor. When parent–child interactions are optimal, prematurity carries a reduced risk of developmental disability.

Children growing up in poverty experience multiple levels of developmental risk: increased exposure to biologic risk factors, such as environmental lead and undernutrition, lack of stimulation in the home, and decreased access to interventional education and therapeutic experiences. As they respond by withdrawal or acting out, they further discourage positive stimulation from those around them.

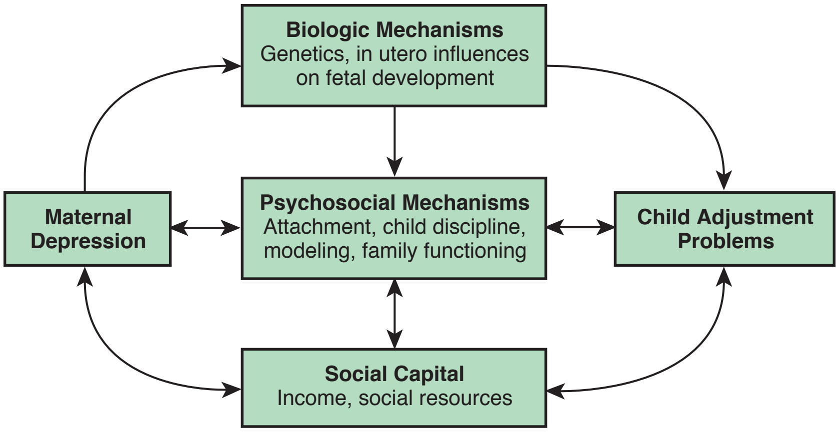

Figure 6-3 Theoretical model of mutual influences on maternal depression and child adjustment. *(From Elgar FJ, McGrath PJ, Waschbusch DA, et al: Mutual influences on maternal depression and child adjustment problems,* Clin Psychol Rev *24:441–459, 2004.)*

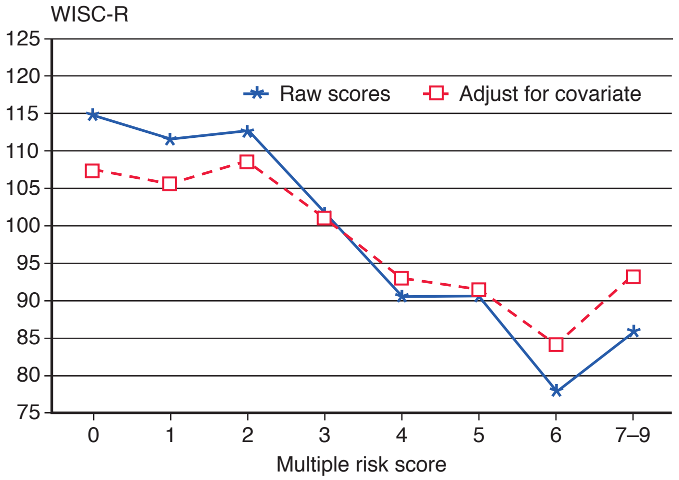

Figure 6-4 Relationship between mean IQ scores at 13 yr (both raw and adjusted for covariation of mother's IQ), as related to the number of risk factors. *WISC-R,* Wechsler Intelligence Scale-Revised. *(From Sameroff AJ, Seifer R, Baldwin A, et al: Stability of intelligence from preschool to adolescence; the influence of social and family risk factors,* Child Dev *64:80–97, 1993.)*

Children of adolescent mothers are also at risk. When early intervention programs provide timely, intensive, comprehensive, and prolonged services, at-risk children show marked and sustained upswings in their developmental trajectory. Early identification of children at developmental risk, along with early intervention to support parenting, is critically important.

An estimate of developmental risk can begin with a tally of risk factors, such as low income, limited parental education, and lack of neighborhood resources. There is a direct relationship between developmental outcome at age 13 yr and the number of social and family risk factors at age 4 yr (Fig. 6-4). Both individual stress and community-level poverty and disorder are associated with shortened telomeres in salivary samples, a link to health disparities. Protective (resilience) factors must also be considered. These factors, like risk factors, may be either biologic (temperamental persistence, athletic talent) or social. The personal histories of children who overcome poverty often include at least 1 trusted adult (parent, grandparent, teacher) with whom the child has a special, supportive, close relationship.

Developmental Domains and Theories of Emotion and Cognition

Child development can also be tracked by the child's developmental progress in particular domains, such as gross motor, fine motor, social, emotional, language, and cognition. Within each of these categories are developmental lines or sequences of changes leading up to particular attainments. Developmental lines in the gross motor domain, leading from rolling to creeping to independent walking, are obvious. Others, such as the line leading to the development of conscience, are more subtle.

The concept of a developmental line implies that a child passes through successive stages. Several psychoanalytic theories are based on stages as qualitatively different epochs in the development of emotion and cognition (Table 6-2). In contrast, behavioral theories rely less on qualitative change and more on the gradual modification of behavior and accumulation of competence.

Psychoanalytic Theories

At the core of **Freudian theory** is the idea of body-centered (or, broadly, "sexual") drives; the emotional health of both the child and the adult depends on adequate resolution of these conflicts. Although Freudian ideas have been challenged, they opened the door to subsequent theories of development.

Erikson recast Freud's stages in terms of the emerging personality (see Table 6-2). The child's sense of basic trust develops through the successful negotiation of infantile needs. As children progress through these psychosocial stages, different issues become salient. It is predictable that a toddler will be preoccupied with establishing a sense of autonomy, whereas a late adolescent may be more focused on establishing meaningful relationships and an occupational identity. Erikson recognized that these stages arise in the context of Western European societal expectations; in other cultures, the salient issues may be quite different.

Erikson's work calls attention to the intrapersonal challenges facing children at different ages in a way that facilitates professional intervention. Knowing that the salient issue for school-age children is industry vs inferiority, pediatricians inquire about a child's experiences of mastery and failure and (if necessary) suggest ways to ensure adequate successes.

Cognitive Theories

Cognitive development is best understood through the work of **Piaget**. A central tenet of Piaget's work is that cognition changes in quality, not just quantity (see Table 6-2). During the sensorimotor stage, an infant's thinking is tied to immediate sensations and a child's ability to manipulate objects. The concept of "in" is embodied in a child's act of putting a block into a cup. With the arrival of language, the nature of thinking changes dramatically; symbols increasingly take the place of objects and actions. Piaget described how children actively construct knowledge for themselves through the linked processes of assimilation (taking in new experiences according to existing schemata) and accommodation (creating new patterns of understanding to adapt to new information). In this way, children are continually and actively reorganizing cognitive processes.

Table 6-2 Classic Stage Theories

	INFANCY (0-1 YR)	TODDLERHOOD (2-3 YR)	PRESCHOOL (3-6 YR)	SCHOOL AGE (6-12 YR)	ADOLESCENCE (12-20 YR)
Freud: psychosexual	Oral	Anal	Phallic/oedipal	Latency	Genital
Erikson: psychosocial	Basic trust vs mistrust	Autonomy vs shame and doubt	Initiative vs guilt	Industry vs inferiority	Identity vs role diffusion
Piaget: cognitive	Sensorimotor	Sensorimotor	Preoperational	Concrete operations	Formal operations
Kohlberg: moral	—	Preconventional: avoid punishment/obtain rewards (stages 1 and 2)	Conventional: conformity (stage 3)	Conventional: law and order (stage 4)	Postconventional: moral principles

Piaget's basic concepts have held up well. Challenges have included questions about the timing of various stages and the extent to which context may affect conclusions about cognitive stage. Children's understanding of cause and effect may be considerably more advanced in the context of sibling relationships than in the manipulation and perception of inanimate objects. In many children, logical thinking appears well before puberty, the age postulated by Piaget. Of undeniable importance is Piaget's focus on cognition as a subject of empirical study, the universality of the progression of cognitive stages, and the image of a child as actively and creatively interpreting the world.

Piaget's work is of special importance to pediatricians for 3 reasons: (1) Piaget's observations provide insight into many puzzling behaviors of infancy, such as the common exacerbation of sleep problems at 9 and 18 mo of age. (2) Piaget's observations often lend themselves to quick replication in the office, with little special equipment. (3) Open-ended questioning, based on Piaget's work, can provide insights into children's understanding of illness and hospitalization.

Based on cognitive development, **Kohlberg** developed a theory of moral development in 6 stages, from early childhood through adulthood. Preschoolers' earliest sense of right and wrong is egocentric, motivated by externally applied controls. In later stages, children perceive equality, fairness, and reciprocity in their understanding of interpersonal interactions through perspective-taking. Most youth will reach stage 4, conventional morality, by mid to late adolescence. The basic theory has been modified to distinguish morality from social conventions. Whereas moral thinking considers interpersonal interactions, justice, and human welfare, social conventions are the agreed-on standards of behavior particular to a social or cultural group. Within each stage of development, children are guided by the basic precepts of moral behavior, but also may take into account local standards, such as dress code, classroom behavior, and dating expectations. Additional studies have even demonstrated some protomorality in infants.

Behavioral Theory

This theoretical perspective distinguishes itself by its lack of concern with a child's inner experience. Its sole focus is on observable behaviors and measurable factors that either increase or decrease the frequency with which these behaviors occur. No stages are implied; children, adults, and, indeed, animals all respond in the same way. In its simplest form, the behaviorist orientation asserts that behaviors that are positively reinforced occur more frequently; behaviors that are negatively reinforced or ignored occur less frequently. The strengths of this position are its simplicity, wide applicability, and conduciveness to scientific verification. A behavioral approach lends itself to interventions for various common problems, such as temper tantrums, aggressive preschool behavior, and eating disorders in which behaviors are broken down into discrete units. In cognitively limited children and children with autism spectrum disorders (see Chapter 30), behavioral interventions using **applied behavior analysis** approaches have demonstrated their ability to teach new, complex behaviors. Applied behavior analysis has been particularly useful in the treatment of early-diagnosed autism (see Chapter 30.1). However, in cases in which misbehavior is symptomatic of an underlying emotional, perceptual, or family problem, an exclusive reliance on behavior therapy risks leaving the cause untreated. Behavioral approaches can be taught to parents to apply at home.

Theories Commonly Employed in Behavioral Interventions

An increasing number of programs or interventions (within and outside of the physician's office) are designed to influence behavior; some of these models are based on behavioral or cognitive theory or may have attributes of both. The most commonly employed models are the Health Belief Model, Theory of Reasoned Action, Theory of Planned Behavior, Social Cognitive Theory, and the Transtheoretical Model, which is also known as Stages of Change Theory. Pediatricians should be aware of these models; Table 6-3 shows the similarities and differences between these models. Interventions based on these theories have been designed for children and adolescents in community, clinic, and hospital-based settings.

Motivational interviewing is a technique often used in clinical settings to bring about behavior change, rather than a behavioral theory. The goal in using the technique is to enhance an individual's motivation to change behavior by exploring and removing ambivalence. This may be practiced by an individual practitioner and is taught in some pediatric residency programs. Motivational interviewing emphasizes the importance of the therapist (which may be a pediatrician, other physician, psychologist, social worker, etc.) understanding the client's perspective and displaying unconditional support. The therapist is a partner rather than an authority figure and recognizes that, ultimately, the patient has control over the patient's choices.

Statistics Used in Describing Growth and Development

(See Chapters 15 and 16.)

In everyday use, the term *normal* is synonymous with *healthy*. In a statistical sense, *normal* means that a set of values generates a normal (bell-shaped or gaussian) distribution. This is the case with anthropometric quantities, such as height and weight, and with many developmental milestones, such as the age of independent standing. For a **normally distributed measurement**, a histogram with the quantity (height, age) on the *x*-axis and the frequency (the number of children of that height, or the number who stand on their own at that age) on the *y*-axis generates a bell-shaped curve. In an ideal bell-shaped curve, the peak corresponds to the arithmetic mean (average) of the sample and to the median and the mode as well. The **median** is the value above and below which 50% of the observations lie; the mode is the value having the highest number of observations. Distributions are termed *skewed* if the mean, median, and mode are not the same number.

The extent to which observed values cluster near the mean determines the width of the bell and can be described mathematically by the **standard deviation (SD)**. In the ideal normal curve, a range of values extending from 1 SD below the mean to 1 SD above the mean includes approximately 68% of the values, and each "tail" above and

Table 6-3 Similar or Identical Elements Within 5 Health-Behavior Theories

CONCEPT	GENERAL TENET OF THE CONCEPT "ENGAGING IN THE BEHAVIOR IS LIKELY IF …"	HEALTH BELIEF MODEL	THEORY OF REASONED ACTION	THEORY OF PLANNED BEHAVIOR	SOCIAL COGNITIVE THEORY	TRANSTHEORETICAL MODEL
ATTITUDINAL BELIEFS						
Appraisal of the positive and negative aspects of the behavior and expected outcome of the behavior	The positive aspects outweigh the negative aspects	Benefits, barriers/ health motive	Behavioral beliefs and evaluation of those beliefs (attitudes)	Behavioral beliefs and evaluation of those beliefs (attitudes)	Outcome expectations/ expectancies	Pros, cons (decisional balance)
SELF-EFFICACY BELIEFS/BELIEFS ABOUT CONTROL OVER THE BEHAVIOR						
Belief in one's ability to perform the behavior; confidence	One believes in their ability to perform the behavior	Self-efficacy	—	Perceived behavioral control	Self-efficacy	Self-efficacy/temptation
NORMATIVE AND NORM-RELATED BELIEFS AND ACTIVITIES						
Belief that others want you to engage in the behavior (and one's motivation to comply); may include actual support of others	One believes that people important to one want one to engage in the behavior; person has others' support	Cues from media, friends (cues to action)	Normative beliefs and motivation to comply (subjective norms)	Normative beliefs and motivation to comply (subjective norms)	Social support	Helping relationships (process of change)
Belief that others (e.g., peers) are engaging in the behavior	One believes that other people are engaging in the behavior	—	—	—	Social environment/ norms; modeling	Social liberation (process of change)
Responses to one's behavior that increase or decrease the likelihood one will engage in the behavior; may include reminders	One receives positive reinforcement from others or creates positive reinforcements for one's self	Cues from media, friends (cues to action)	—	—	Reinforcement	Reinforcement management/stimulus control (processes of change)
RISK-RELATED BELIEFS AND EMOTIONAL RESPONSES						
Belief that one is at risk if one does not engage in the behavior, and that the consequences may be severe; may include actually experiencing negative emotions or symptoms and coping with them	One feels at risk with regard to a negative outcome or disease	Perceived susceptibility/ severity (perceived threat)	—	—	Emotional coping responses/ expectancies about environmental cues	Dramatic relief (process of change)
INTENTION/COMMITMENT/PLANNING						
Intending or planning to perform the behavior; setting goals or making a commitment to perform the behavior	One has formed strong behavioral intentions to engage in the behavior; one has set realistic goals or made a firm commitment to engage in the behavior	—	Behavioral intentions	Behavioral intentions	Self-control/ self-regulation	Contemplation/ preparation (stages of change); self-liberation (process of change)

From Noar SM, Zimmerman RS: Health behavior theory and cumulative knowledge regarding health behaviors: are we moving in the right direction? Health Educ Res *20:275–290, 2005, Table 1.*

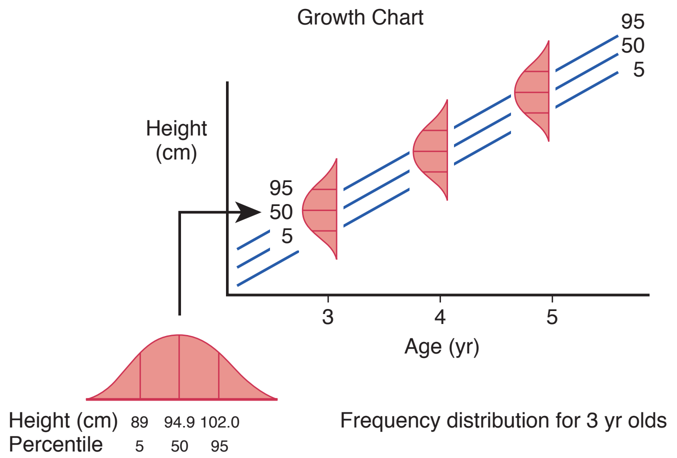

Figure 6-5 Relationship between percentile lines on the growth curve and frequency distributions of height at different ages.

Table 6-4 Relationship Between SD and Normal Range for Normally Distributed Quantities

OBSERVATIONS INCLUDED IN THE NORMAL RANGE		PROBABILITY OF A "NORMAL" MEASUREMENT DEVIATING FROM THE MEAN BY THIS AMOUNT	
SD	**%**	**SD**	**%**
±1	68.3	≥1	16.0
±2	95.4	≥2	2.3
±3	99.7	≥3	0.13

below that range contains 16% of the values. A range encompassing ±2 SD includes 95% of the values (with the upper and lower tails each comprising approximately 2.5% of the values), and ±3 SD encompasses 99.7% of the values (Table 6-4 and Fig. 6-5).

For any single measurement, its distance away from the mean can be expressed in terms of the number of SDs (also called a *z score*); one can then consult a table of the normal distribution to find out what percentage of measurements fall within that distance from the mean. Software to convert anthropometric data into z scores for epidemiologic purposes is available. A measurement that falls "outside the normal range"—arbitrarily defined as 2, or sometimes 3, SDs on either side of the mean—is atypical, but not necessarily indicative of illness. The further a measurement (say, height, weight, or IQ) falls from the mean, the greater the probability that it represents not simply normal variation, but rather a different, potentially pathologic, condition.

Another way of relating an individual to a group uses percentiles. The **percentile** is the percentage of individuals in the group who have achieved a certain measured quantity (e.g., a height of 95 cm) or a developmental milestone (e.g., walking independently). For anthropometric data, the percentile cutoffs can be calculated from the mean and SD. The 5th, 10th, and 25th percentiles correspond to −1.65 SD, −1.3 SD, and −0.7 SD, respectively. Figure 6-4 demonstrates how frequency distributions of a particular parameter (height) at different ages relate to the percentile lines on the growth curve.

Chapter 7

Cognitive Development: Domains and Theories

Alison Gopnik

From Freud to Skinner to Piaget, philosophers, psychologists, and psychiatrists used to think that babies and young children were solipsistic and egocentric, precausal and illogical, concrete and superficial, restricted to the immediate here and now. That is still the picture most parents and many pediatricians have of babies and young children.

But 3 decades of research shows that just the opposite is true. Even the youngest babies both know more and learn more than we would ever have thought. There are still many controversies about exactly what babies and children know and when they know it. There also are competing theories about how and why children know and learn so much.

METHODOLOGIES

Much of this new understanding is the result of new techniques. Psychoanalysts asked adults to remember their childhood, behaviorists extrapolated from experiments on animals, and even Jean Piaget, the founder of the field of cognitive development, relied on observing the spontaneous behavior of babies, or on clinical interviews in which he asked children to say what they thought about mind and body or life and death. We now have experimental techniques that let children tell us what they know in their own language.

One group of methods involves seeing what babies prefer to look at (visual preferences), or listen to, or even smell. Babies have a choice of two stimuli, such as a mother's voice playing in one speaker, while a stranger's plays in another. We can see if babies turn toward one stimuli or the other.

Other methods use the fact that babies pay more attention to things that are unexpected than to those that are more predictable or familiar. Babies are *habituated* to a stimulus; they look or listen until their attention wanders, and when they see a variant of that stimulus they focus attention to the new stimulus if it is different. In *violation-of-expectation* studies, experimenters present babies with events that are surprising from an adult point of view, for example, one object apparently moving through another, and see whether babies look longer at those events than at similar unsurprising events.

These *looking-time* techniques have a drawback: it is difficult to tell just how babies interpret the stimulus by simply recording whether they look at it. Other technologies have made it possible to actually track babies' eye movements as they look at a stimulus. We can also look at what babies do as well as at what they attend to. Watching where babies reach or what they point to can be highly informative. Babies begin to imitate other people literally from birth and seeing how that imitation unfolds has proved to be a particularly useful tool.

As children grow older their attention patterns become less predictable. On the other hand, we can listen to what toddlers and preschoolers say. Large databases that record and analyze children's spontaneous language are becoming increasingly sophisticated, and can be an invaluable source of insight.

Asking preschoolers what they think often produces a sort of stream-of-consciousness poem, and has undoubtedly contributed to the impression that preschoolers are irrational. Children behave much more intelligently when you ask them about restricted, highly detailed scenarios. Instead of asking "Can someone believe something that isn't true?," researchers tell children a specific story—Max sees some

chocolate in the yellow cupboard, but then it is transferred to the blue cupboard without his knowledge. Preschoolers are even likely to respond to open-ended questions with silence or irrelevance. But they will consistently pick one option over the other when you ask them to choose between them. Four-year-olds can say that Max will look for the chocolate in the blue cupboard rather than the yellow one.

PHYSICAL KNOWLEDGE DEVELOPMENT

From the time infants are very young they understand some of the basic properties of physical objects. In the first few months of life, they know that objects are 3-dimensional and extended in space, that they can't pass through other objects, and that they continue to exist when they move behind a screen. They also have a basic concept of numbers, at least up to 3. In one experiment, infants see a toy disappear behind a screen, and then see another toy move behind the screen. The screen is lifted and 1, 2, or 3 toys appear. The babies look longer if 1 or 3, rather than 2, toys appear.

Infants also have a surprisingly early understanding of relationships that cross sensory modalities. They recognize parallelisms between lip movements and vocal sounds, between the feel of a pacifier and the way it looks, or between the visual image of a bouncing ball and the sound it makes.

Babies also have a surprisingly early and sophisticated understanding of statistics and probability. Before they are 1 yr old, they expect that a ball taken at random from a box of 80 red and 20 white balls is more likely to be red than white. Infants can also recognize statistical patterns in both visual and auditory sequences. You can play babies a string of syllables or tones or show them a sequence of pictures that have a particular pattern. For example “pa” may always follow “ti” but only follow “ko” 75% of the time. Babies seem to figure out these statistical patterns. Later they use them to isolate words or objects or other meaningful units from the torrent of sounds and sights they perceive.

In their second year, babies have a basic understanding of spatial relationships like gravity and containment. They can also categorize objects, recognizing that animals, for example, go together and are different from artifacts. They also gradually come to understand how to use simple tools to accomplish what they want, although they may still make interesting mistakes, like pulling a blanket to try to get a toy even when the toy is beside the blanket instead of on top of it.

Preschoolers continue to learn about the physical world, but they also begin to learn about the biologic world. Three and 4 yr olds are *essentialists*. They assume that categories of animals or plants, such as birds or daisies, will have the same insides and the same *essence* even if they are perceptually diverse. Contrary to conventional wisdom, preschoolers are not restricted to superficial perceptual categories. Preschoolers also have a first understanding of basic biologic ideas like inheritance, growth, and illness, and don't confuse these with psychologic ideas; they are not animists as Piaget thought. However, they still have difficulty understanding biologic concepts in a unified way, and they have little understanding of death.

By 5 yr of age, preschoolers have a more unified concept of something like a *life force*. They believe that the presence of this force makes living things grow and thrive, and its absence leads to illness and death. Interestingly, disadvantaged rural children, for example, Native American children on Indian reservations, who may have more experience of the living world, may develop an understanding of biology earlier than more privileged middle-class children.

Preschoolers also have a much more sophisticated understanding of causal relationships than we previously thought. Infants even understand something about the way physical objects move and interact with other objects. Older children understand the mechanics of simple physical systems.

They can also learn about new causal relationships. We can give young children evidence about how a novel machine works, showing them for instance that a box lights up and plays music only when you put a specific combinations of blocks on it. Children as young as 2 yr of age can figure out how the machine works and can use that information to invent novel ways to make it go. By 4 yr, they can figure out a machine that involves complex interactions of 3 different gears and switches. They can even propose invisible unobserved causes, when that is the best explanation for the pattern of evidence. In fact, they use forms of inductive causal reasoning that are basic to science and that are used in computer learning.

SOCIAL KNOWLEDGE DEVELOPMENT

Some of the most impressive kinds of early knowledge and learning involve children's understanding of other people. These *theory-of-mind* abilities are particularly important for social interaction and appear to be specifically impaired in children with autism. From the time they are born, infants treat people as special. Within the 1st mo infants prefer to look at human faces and listen to human voices, and rapidly prefer the face, voice, and even smell of their caregivers. Newborn infants also imitate facial expressions. To do this they must link what they see on the face of another person and how it feels to be them inside.

Within the 1st yr babies develop an even richer understanding of others. Seven-month-olds appreciate that human actions are directed towards particular goals. You can show the babies a ball and a teddy bear on a table. A hand reaches in and grasps the ball. Now you switch the locations of the 2 toys, so that the teddy bear is where the ball was and vice-versa. Seven-month-olds look longer when the hand goes to the teddy bear instead of the ball. They don't do this if a stick, rather than a hand, touches one object or the other.

One-year-olds don't just imitate actions; they reproduce the results of those actions. A 1 yr old child walks into the lab and sees the experimenter tap his head on a box, making the box light up. A week later she returns to the lab and sees the box on the table. She'll immediately use her own head to get the box to light.

Eighteen-month-olds can imitate in an even more sophisticated way. You can show them an experimenter touching her head to the box, but now she has a blanket wrapped around her so that her hands aren't available. If the other person's hands are free the babies will tap their own heads on the machine. But if she's wrapped up in the blanket and she taps the machine with her head, the babies will instead use their own hands. They've figured out that you would use your hands if you could, but because you can't, you're using your head instead.

In their second year, children also start to understand that their own perceptions, attention, and emotion may be shared by others. At this age babies start to engage in *joint attention behaviors*; they will follow the gaze or point of another person and they will point to objects themselves. They also start to understand that closing your eyes or wearing a blindfold may make it more difficult to see. In *social referencing*, babies will react appropriately to the emotional expression of another person that is directed at an object; if 1 yr olds see someone react to an ambiguous object with fear they will avoid the object themselves.

Babies are also sensitive to the contingency between their own actions and the actions of others, and use contingency patterns to differentiate people and things. If 1 yr olds see a machine that blinks and chirps in coordination with their own actions, they will treat it like a person, following its gaze if it turns toward an object. They will not do this if the machine makes the same noises, but they are not contingent on the baby's actions.

Eighteen-month-olds also start to show an understanding of love. *Attachment* researchers have long noted that different babies behave differently when they are separated from their caregivers and then reunited. *Secure* babies are distressed at separation but are quickly comforted when the caregiver returns. *Avoidant* babies seem to repress their distress; they ignore the caregiver both when she leaves and returns. *Anxious* babies are very distressed and take a long time to comfort.

Secure and insecure babies seem to have different theories of love. In one experiment, 18 mo old babies saw an animated film of a mother figure, a big circle, and a baby figure, which was a small circle that emitted a realistic cry. Then the babies either saw that the mother move toward the baby or move away from the baby. The secure babies expected that the mother would return to the baby and looked longer when she did not. The insecure babies had just the opposite theory; they looked longer when the mother changed course and returned.

From 2-6 yr of age, children discover further fundamental facts about how their own minds and the minds of others work. Even 18 mo olds already seem to understand something about the ways that people's minds might differ. You can show 14 mo olds and 18 mo olds 2 bowls of food: raw broccoli and Goldfish crackers. Then the experimenter tastes a bit of food from each bowl and acts as if she likes the broccoli but not the crackers. She puts out her hand and says, "Can you give me some." Fourteen-month-olds give the experimenter the crackers, but the 18 mo olds give the experimenter broccoli.

Slightly older children can understand the complex causal interactions between desire, perception, and emotion; they can predict all the possible actions that might stem from different psychologic combinations.

Preschoolers also, against conventional wisdom, can understand the difference between the physical and the mental, reality and fantasy, from a very young age. Preschoolers may be intensely emotionally affected by the products of fantasy, from imaginary friends to monsters in the closet. Nevertheless, they recognize the distinction between imaginations, which are private and intangible, and reality, which is public and verifiable.

In addition, around 5 yr of age children start to understand the relationship between our beliefs and the world around us. For example, suppose you show a child a candy box that turns out to be full of pencils. The children are very surprised when they see the pencils. But if you ask them what they thought was in the box 3 yr olds confidently report that they thought there were pencils in there. You see the same thing in the "Max" experiment described earlier. Though 4 yr olds accurately report where Max will look for the chocolate, 3 yr olds say that Max will look for the chocolate where it actually is instead of where he thinks it is.

Similarly, 3 yr olds have difficulty understanding the sources of their beliefs. If you ask them how they learned something, they are likely to think that they saw it directly, even when they actually heard it from someone else—an important consideration in child testimony. In their spontaneous language children only start explaining actions in terms of thoughts and beliefs, especially false thoughts and beliefs, when they are around 4 yr old. There are somewhat controversial studies that suggest that some implicit and unconscious understanding of belief may even be in place earlier, but there are clearly important changes in children's conscious understanding of the mind between 3 and 5 yr of age.

Understanding the mind also allows children to act to change the minds of others. Children who can explain actions in terms of a theory of mind also seem to be more adept, for good or ill, at altering other people's minds. They are more socially skillful, but they are also better liars.

Understanding minds actually also allows us to change our own minds as well as the minds of others. Between 3 and 5 yr of age, children also start to develop capacities for what psychologists call *executive control*, which is the ability to control your own actions, thoughts, and feelings. These capacities seem to be specifically related to *theory-of-mind* abilities. Understanding how your own mind works may help you to control and regulate it.

THEORIES OF COGNITIVE DEVELOPMENT

Several alternative theories have been proposed to explain these developmental processes. The basic conundrum of cognitive development is that even the youngest babies seem to have abstract, highly structured, hierarchical knowledge of the world; knowledge that lets them make wide-ranging new inferences. And yet as children experience more of the world, these representations change in systematic ways; it appears that young children are learning from their experiences.

One classic approach, often called *nativism* suggests that much of this abstract structure is in place innately; babies are born knowing about crucial aspects of the world. Learning is largely just a matter of filling in details. Although babies are far from being blank slates, there also seem to be significant changes in their understanding of the world.

The alternative approach, *empiricism,* suggests that all of children's knowledge is simply the result of a process of associating or combining particular sensory experiences, or detecting the statistics of the environment. Although children are able to associate particular experiences and to detect statistics, those abilities don't seem to be sufficient to explain their remarkable growth of knowledge.

Piaget originally articulated *constructivism* as an alternative to both nativism and empiricism. But Piaget had little to say in detail about how constructivist processes could take place; many of his empirical claims have been disproved. The *theory theory* is the more current version of constructivism. The idea is that children develop their knowledge of the world by constructing every day or intuitive theories, much like scientific theories. The *theory theory*, unlike empiricism, proposes that even babies may be born with innate theories of the world, but unlike nativism, it proposes that those theories may be radically transformed as children learn more about the world. Most recently, *rational constructivism*, a more rigorous and precise version of the *theory theory*, was formulated. It uses mathematical ideas about probabilistic models and bayesian inference to explain how even very young children can learn so much from the evidence they encounter.

Within the constructivist approach, an exciting new set of studies and theoretical ideas confirms something that parents and preschool teachers and others have long thought intuitively: Very young children's play, both their exploratory play and their imaginative and pretend play, contributes greatly to their early learning.

Nativism, empiricism, and constructivism all focus on the process of learning from evidence. Two other approaches describe other factors that contribute to cognitive development. Information-processing approaches stress the development of general abilities to process and organize information, such as memory or attention. Indeed, children do develop such abilities in the first few years of life and those developments contribute to the development of their knowledge.

Sociocultural approaches emphasize the contribution that *expert adults* can make to children's knowledge. There is growing evidence that from very early in infancy babies are specifically and powerfully tuned to information that comes to them from their caregivers. By preschool, what is sometimes called *implicit* or *intuitive* pedagogy plays an increasingly important role in children's learning. Preschoolers tend to give grownup testimony the benefit of the doubt, but they can also distinguish between reliable and unreliable teachers.

However, preschoolers sensitivity to implicit teaching can be a double-edged sword. Some studies show that children are less likely to engage in wide-ranging exploration when adults provide them with answers. Preschoolers left to their own resources are often able to solve complex problems (see Chapter 7.1). In addition because play is such an important component of a preschool-age child's learning process, the learning environment may need to be less structured, more child-focused, and with less emphasis on traditional academic instruction. Sociocultural approaches are especially relevant to the many kinds of learning where there is no right answer such as learning the particular traditions, mythologies, or values of your cultural or ethnic group.

All these factors, innate structure, association and statistics, theory formation and play, information-processing abilities, and cultural transmission, must somehow combine to allow children to learn as much as they do.

Box 7-1 Example of Creating an Educational Environment That Recognizes the Child's Social–Emotional Well-Being

The K3 children were working on building an igloo in the playground. When they realized the task was bigger than they anticipated, they decided to invite their parents to help.

M (4 yr old) shared that his dad could not come because he was in the hospital. The teacher dialogued with the child, and together they thought about ways for the father to be part of the process. The decision was to create a book for his father with the story of the igloo. The strong message given to the child was that he has the tools for coping with the situation. This empowered him to approach the situation with joy and creativity. One of the child's ideas was to add some photos of his father's previous visits at school to the book. Seen as competent, he chose the pictures that would go into the pages.

M was so proud of his book. He asked every person who visited our school, whether adult or child, to read his book with him. In addition this book brought emotional stability to a family going through a difficult and scary time. The book was a tool for father and son to communicate and share meaningful conversation.

major elements: the emotional component, the ethical component, and the aesthetic component.

THE EMOTIONAL COMPONENT

Malaguzzi believed that the concept of well-being leads the educational approach. Well-being, especially in early childhood, is the leading developmental task that every child from birth is thriving for as part of each child's sense of self establishment. Creating an educational environment that recognizes the child's social–emotional well-being means creating a place where every child is valued and respected as an individual and as an equal member of a group. Malaguzzi believed that every moment should be enjoyable and satisfactory (Box 7-1).

THE ETHICAL COMPONENT

The following points characterize the Reggio Emilia ethical code:

- Education is not just a technique but is a shared process for revealing values.
- The school is a place that transmits and constructs culture through experiences. The reciprocal relations between transmission and construction gives schools and teachers a responsibility and an active role in sustaining and generating a culture that is based on the past, yet looking ahead to the future.
- The school should focus not only on knowledge but also on concepts, ideas, and values.
- The educator influences the future, and as such needs to generate the connections between the individual and the world.
- Children are born with myriad ways to construct and process knowledge. Those ways are defined as *100 languages*; language is defined as the different ways through which any human being represents, communicates, and expresses thoughts, feelings, concepts, and symbols (Box 7-2).

THE AESTHETIC COMPONENT

Education must focus on the aesthetics because the child knows how to value beauty and is able to interact with all the expressive languages. Malaguzzi's innovative idea for approaching and embracing the expressive–aesthetic aspects to early childhood education was the *atelier*. The atelier is a statement about the importance of imagination, creativity, expression, and aesthetics in the learning and knowledge construction processes. Because children do not separate different disciplinary fields, and because they learn in an interrelated and interdisciplinary way, the learning environment should connect between aesthetics and ways of knowing. The expressive languages and the arts are ways to break the conformist thinking about children and their learning, and to move toward elaborating the opportunities that are given to children while they are exploring, researching, and constructing knowledge.

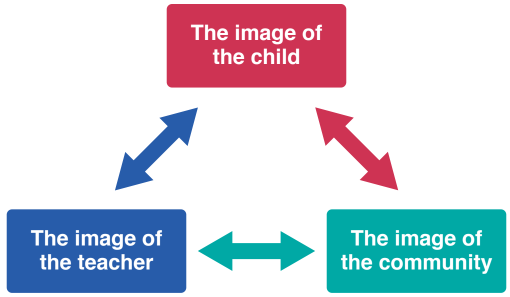

Figure 7-1 Pedagogic thinking: core concepts around 3 major areas.

Box 7-2 Example of Children Processing Information and Solving Problems

When the K4 teacher had an idea to have senior citizens as pen pals for the K4 kids, she thought about a correspondence that might take place every once in a while.

One cold winter day the bus arrived with the seniors for the monthly visit, but the driver notified the school that the bus needed to leave because the lift to lower the seniors off the bus was jammed. When the children heard about the situation, they immediately thought about a way to solve it. They decided as a group to board the bus with the activities that they had planned. They put on their coats and hats and brought the bingo and the brownies, and for the next 2 hr, the children and seniors had an enjoyable afternoon together. It was a moment when we realized that our children have internalized the value of working with seniors and from that place found the appropriate solution to the issue at hand.

PEDAGOGIC THINKING: CORE CONCEPTS AROUND 3 MAJOR AREAS

One of the cornerstones of this approach is the concept of **images** (Fig. 7-1).

An image is a cognitive structure that serves as a container. It keeps and holds all of the tools we have to perceive and interpret the world around us. All of the perceptions and interpretations are organized into clusters that serve as our inner compass and navigate our way in the personal and social–cultural life that we share with others.

When it comes to education, the images play a crucial and determinative role as is reflected in the following quote from Carla Rinaldi: "Everyone (you, us, each parent…) has his or her own image of the child, and, consequently, we have our own educational theories that we develop based on personal, social, cultural, and political experience, and that we construct or acquire as part of our society and culture. Whether we are aware of it or not, we cannot live without theories." Yet, as educators we have a profound responsibility for the awareness level that guides us when we make choices for children.

It is important to note that each person has his or her own image of the child. By saying image we mean personal interpretation that is subjective and unique. The focus is on which point of view being used when thinking about a child. Our points of view about the world around us are dynamic and are consistently changing. We are structuring the impressions we are getting on any concept or experience to create a holistic image in our mind.

The Image of the Child

Loris Malaguzzi said "Each has inside ourselves an image of the child that directs you as you begin to relate to a child. This theory within you pushes you to behave in certain ways." It orients you when you listen to the child, observe the child. It is very difficult for you to act contrary to this internal image.

It is important to emphasize the impact of the image to the awareness of the teachers, as only the awareness would enable the teacher to follow the desired image of children; one that sees and accepts the

Box 7-3 Example of Relating to a Child as a Competent Partner

One day, a child who was questioning about how he is seen by his teacher began to cry, saying, "I cannot do it," referring to pulling on his pants. The teacher who understood it was a question more than a statement about his incompetence, said: "Show me what you **can** do." Her focusing on her perception of the child as competent met the child's inner question and empowered the child to focus on what the child could accomplish. The child was able to complete the task on his own.

child as an active competent partner, plentiful with potential and capabilities. Usually the strength and the talents of children are underestimated and schools tend to suppress the child's potential by creating an environment of transmission, instead of exploration. The environment should be collaborative between teachers and children; they partner together rather than the teacher determining all activities or interactions.

The concept of a "blank slate," first mentioned by the philosopher John Locke, is presented here as a characterizing traditional point of view in education that does not believe in the child's abilities and leaves no room for the child's feelings, thoughts, imagination, and creativity. It also reflects the belief that the child is waiting for the school and society to "write" on, nourish, and fill his or her slate.

Choosing an image calls for a *sense of responsibility*, as we need to commit to the image that was chosen. The chosen image then becomes a compass that guides us in every interaction or practice we are having with the child. Reggio educators believe that the image of **child as competent** brings a point of view that sees children as structuring their sense of self, they generate and construct values, and they establish their rights; the first one is the right that acknowledges and accepts the role childhood has and the unique contribution each person brings to it.

The child is born as a *researcher* that is looking for relationships, hypotheses, and provocations in anything the child is exploring. The choice to see the child as a researcher has major pedagogic implications. The first guiding implication is the understanding that the child is **never** waiting for the adult to actuate the child's need to research, yet the child needs the adult as a **context** for the child's revelations (Box 7-3).

The Image of the Educator

The core component in the image of the teacher is the understanding that to be a high-quality teacher, the educator needs to perceive himself or herself also as a learner. The most meaningful place for learning how to teach is within the educational setting. You learn how to teach by being with children and by reflecting on the processes you have experienced with them; the best key for learning and teaching is **reciprocity**.

The role of the teacher in the above image encompasses the following aspects:

- To define and create the context within which all learning/ teaching processes would occur. The context enables the landscape of learning to emerge and develop.
- To think and plan using symbols and concepts
- To interpret the child concepts and symbols with the group
- To elaborate on the experiences and the interpretations done with the children.
- To review with the children a second round of experiences built on the previous day.
- To add improvisations according to the previous learning processes.

There are reciprocal relationships between the image of the child and the image of the teacher, and each is complementary and bound to the other.

Teachers should never think of the child in the abstract. When we think about a child, that child is already tightly connected and linked to a certain reality. Children have relationships and experiences that they bring to any new environment. Similarly, the teacher brings pieces of his or her life to the educational environment (Box 7-4).

Box 7-4 Example of Reciprocal Relationships Between the Image of the Child and the Image of the Teacher

One morning a child was brought to school and was not willing to take his coat off. The mother did not know how to convince him to take the coat off; the teacher kept asking him to take the coat off; and the child was crying and determined not to take the coat off.

It was only when the teacher changed her **point of view** and was willing to accept the child and meet him where he was that the child stopped crying and was able to join his class activities.

We see this example as a compass for remembering that it is only when you leave your preconceived notions and see yourself as a **place** where children feel that they are seen and heard as equal, active, and competent partners that the quality of relationships you create is elevated and becomes clear and coherent.

The Image of the Contextual Community

The concept at the core of the educational communal life is the idea of the "other" that is the essence of the Reggio Emilia pedagogic approach. The "other" might be the child, the family, or a colleague—in a sense, any person who is interacting with the educational system. All members together, through the relations that are constructed among all, are part of creating a sense of belonging for the system and for its members. The feeling of belonging serves as a foundation for the community life. When people who are part of the system feel they are seen, heard, and known, a culture of participation can be developed. The culture of participation arises out of the integration of the concept of feeling a part of, and its complementary aspect of taking part, and is shared among all children, parents, and teachers.

The focus was and is to develop relationships with the other, with the other's uniqueness and originality, with the other's point of view, and to reach the place where the subjectivity of each partner is open to entering an intersubjective field for a real meeting. The basic assumption is that each family shares its culture with the others.

The idea of crossing the *boundaries of the subjectivity* to arrive at the intersubjective landscape emerges from a very important declaration that the school sends to the community: A declaration of a place that has a defined and solid identity that is based on the perception that the school by nature is a multicultural place, and as such embraces every inhabitant, including each inhabitant's background and culture, knowing that the school point of view is partial, and each is invited to share their points of view, as the school invites each partner to add their point of view for strengthening, elaborating, and accommodating the shared identity of the school.

Concepts like welcoming, plurality, dialog, and intercultural dynamics are explored and new meanings are attributed to them, as a realization that every word/concept or value could have different meanings. That realization creates a place for reworking of the ideas, a place where new questions are generated and discussed.

THE DEVELOPMENTAL THEORIES OF GREENSPAN, VYGOTSKY, AND MALAGUZZI

Greenspan on Well-Being and the Sense of Self

Stanley Greenspan (1941–2010), a psychiatrist, was a leading researcher on the prevention and treatment of emotional and developmental disorders in infants and children. He believed that when you observe or interact with a child, you should take into account not just the child's developmental functioning level, but also the child's background, personal and familial history, and, especially, the quality of relationships the child is experiencing in his or her home and school environment.

Greenspan believed that it is the quality of the interactions children have with meaningful figures that determines the quality of the social–emotional experiences and the level of success in achieving the developmental tasks that are required in every developmental sequence. Greenspan developed a model that shows how in every developmental phase, 2 different processes are possible. Simply stated, high-quality responsive parenting leads to high-quality achievement of the

Table 7-1 Comparison of Greenspan and Malaguzzi Developmental Theories

DEVELOPMENTAL PRINCIPLE	GREENSPAN	MALAGUZZI (REGGIO)
Self-regulation	The ability to reach an inner and outer harmony. The harmony represents the skills needed to create the initial understanding of being in the world.	The school environment is designed and organized in ways that support the concept of being in harmony. In Malaguzzi's words, an "amiable environment."
Attachment and bonding	The ability to create a meaningful, special bond with another; plant the seeds for the notion of to love and be loved.	Well-being is the fountain for all the relationships, and the school is the landscape of well-being that is ready to embrace all kinds of relationships.
Differentiation	The ability to differentiate oneself from any other person is crucial for the sense of separation and uniqueness.	The child is seen as a unique individual, who is at all times an active and equal member of the school community.
Initiation and internalization	The ability to navigate oneself in the world in an active, participatory way, that empowers and leads to the internalization of the sense of self.	One of the core concepts that defines curricular planning and guides teachers' practical choices is the ability of the school to define the educational intents in visible and declarative ways that support the curricular initiatives and their impact on the school community.
Representational thinking	The ability to represent all of the above in a verbal, conceptual, socially and emotionally appropriate way.	The concept of the "hundred languages of children" is a message that there are a hundred ways to represent the knowledge and understanding that was achieved in any learning experience.

developmental tasks needed; and low-quality parenting skills lead to low-quality achievement of the developmental tasks at hand.

The above point of view matches Malaguzzi's concept of the **pedagogy of relationships**. The concept of *pedagogy of relationships* has an extra value for the early childhood period because the early childhood years are considered the most critical period in our lives; the **self** that is the entity that is the core of our being establishes its essential structure in these early years.

Greenspan defined the leading developmental tasks that are connected to the development of the sense of self and that continue to deepen and elaborate throughout life: self-regulation processes, attachment and bonding, differentiation, initiative and internalization, and representational symbolic thinking (Table 7-1).

Vygotsky and the Reggio Emilia Approach

Vygotsky's concept of the **zone of proximal development** states that in any given moment, the person (child or adult) finds himself between 2 developmental points—the *actual* and the *potential* points of development that represent the idea of human competence. Vygotsky saw the actual point of development as the place that reflects the already existing skills in all areas of development, and the potential point of development as the place for the skills on which the person works at that given time. Between those 2 points of development is the land of development, where each of us is using what we already have in order to develop what is potentially waiting to unfold.

Vygotsky believed that the teacher's role is to be with children in a very conscious and attentive way. To use the child's actual point of development as the launching place for challenges that would encourage further exploration and learning.

Malaguzzi believed that being with children in their developmental journey calls for deep engagement and attentiveness by the teacher in order to meet all children individually and in small groups in terms of where they are in their interests, exploration, and research. The main goal is to create the most meaningful learning environment that supports the actualization of their potential. According to Malaguzzi, the level of engagement of the teachers is not narrowed only to their actions but includes investment in observations, interpretations, and reflections that are the grounds for the practical actions.

Vygotsky's social constructive is known for its relevance to the educational field. One of Vygotzky's leading concepts is the scaffolding process that defines a specifi interaction between teachers and learners in which the teacher supports the learning process in situations where the learner cannot explore or research alone. Connected to the scaffolding concept is the question of the relations between scaffolding and giving **help** when it comes to relationships with children. Vygotsky's scaffolding concept highlights the difference between authentic and nonauthentic support of children's learning processes and focuses on giving only the support that would enable the child to move toward the child's potential point of development, according to the child's developmental pace. This was interpreted by Malaguzzi as *things that children can do by themselves should not be done for them*.

It is only when the child needs the bridge between the child's current place and the child's destination that adults should step in delicately and consciously and provide help (Box 7-5).

Box 7-5 Example of Giving Only the Support That Enables a Child to Move Toward the Child's Potential Point of Development, According to the Child's Developmental Pace

The children were playing with a large box that was brought to the school. One of the kids climbed in and suddenly realized he was stuck and could not climb out. The child began to cry. The teacher asked him what he could do to solve the problem, and his response was: "I will ask my friends." He called his friends and they began giving him ideas.

One child tried to pull him out, but the box was too tall. Two other friends came, brought a chair, and tried to pull him out, but still the box was too tall.

Then a fourth child joined and suggested putting a chair INSIDE the box. The children brought a chair that was put inside, and their friend climbed out happy and empowered.

Reggio Approach and Relationships with Parents

In the Reggio approach, the image of the parent parallels the image of the child. In other words, as the child is seen as an equal, active, and competent partner, the parent is also perceived as a competent, active partner to the educational endeavor. The core of the relationship is the value of parent participation with 2 cornerstones. First is the idea of taking part in the different ways parents can participate in school life. Second is the emotional attitude parents establish toward the school. The integration of those 2 cornerstones creates a way of being in the schools that represents a democratic approach to citizenship with solidarity and shared responsibility as core guidelines.

The ethical code for the participatory approach is that each member in the educational process brings his or her forms of knowing, points of view, interpretations of different experiences, and culture. The participation sets the ground to discussions and rich exchanges among the parents and the school that open the door for wide-ranging discussions

and collaborations. The uniqueness of the participatory way of being in the Reggio Emilia approach is the belief that only by accepting other persons from a humanistic point of view, can real acceptance and acknowledgement arise. The parent usually has his or her own image of the child that is based on the relationships, culture, and family traditions, history, and characteristics. The deep relationship with the school enables the parent to gain a different image of his or her child. The opportunity to widen the personal image and to integrate the personal image with the school image opens a door for a wider and deeper relationship between parents and their children.

Chapter 8

Assessment of Fetal Growth and Development

Susan Feigelman

Table 8-1 Milestones of Prenatal Development

WK	DEVELOPMENTAL EVENTS
1	Fertilization and implantation; beginning of *embryonic* period
2	Endoderm and ectoderm appear (bilaminar embryo)
3	First missed menstrual period; mesoderm appears (trilaminar embryo); somites begin to form
4	Neural folds fuse; folding of embryo into human-like shape; arm and leg buds appear; crown-rump length 4-5 mm
5	Lens placodes, primitive mouth, digital rays on hands
6	Primitive nose, philtrum, primary palate
7	Eyelids begin; crown-rump length 2 cm
8	Ovaries and testes distinguishable
9	*Fetal* period begins; crown-rump length 5 cm; weight 8 g
12	External genitals distinguishable
20	Usual lower limit of viability; weight 460 g; length 19 cm
25	Third trimester begins; weight 900 g; length 24 cm
28	Eyes open; fetus turns head down; weight 1,000-1,300 g
38	Term

The developing fetus is affected by social and environmental influences, including maternal nutritional status; substance use (both legal and illicit); and psychologic trauma. Correspondingly, the psychologic alterations experienced by the parents during the gestation profoundly impact the lives of all members of the family. Growing evidence implicates the importance of these and other maternal and paternal experiences that occur during and prior to the pregnancy (and even among members of earlier generations) on the subsequent development of the individual (*epigenetic effects*). The complex interplay between these forces and the somatic and neurologic transformations occurring in the fetus influence growth and behavior at birth, through infancy, and potentially throughout the individual's life.

SOMATIC DEVELOPMENT

Embryonic Period

Table 8-1 lists milestones of prenatal development. By 6 days postconception age, as implantation begins, the embryo consists of a spherical mass of cells with a central cavity (the *blastocyst*). By 2 wk, implantation is complete and the uteroplacental circulation has begun; the embryo has 2 distinct layers, *endoderm* and *ectoderm*, and the amnion has begun to form. By 3 wk, the 3rd primary germ layer *(mesoderm)* has appeared, along with a primitive neural tube and blood vessels. Paired heart tubes have begun to pump.

During wk 4-8, lateral folding of the embryologic plate, followed by growth at the cranial and caudal ends and the budding of arms and legs, produces a human-like shape. Precursors of skeletal muscle and vertebrae (somites) appear, along with the branchial arches that will form the mandible, maxilla, palate, external ear, and other head and neck structures. Lens placodes appear, marking the site of future eyes; the brain grows rapidly. By the end of wk 8, as the embryonic period closes, the rudiments of all major organ systems have developed; the crown-rump length is 3 cm.

Fetal Period

From the 9th wk on (fetal period), somatic changes consist of rapid body growth as well as differentiation of tissues, organs, and organ systems. Figure 8-1 depicts changes in body proportion. By wk 10, the face is recognizably human. The midgut returns to the abdomen from the umbilical cord, rotating counterclockwise to bring the stomach, small intestine, and large intestine into their normal positions. By wk 12, the gender of the external genitals becomes clearly distinguishable. Lung development proceeds, with the budding of bronchi, bronchioles, and successively smaller divisions. By wk 20-24, primitive alveoli have formed and surfactant production has begun; before that time, the absence of alveoli renders the lungs useless as organs of gas exchange.

During the 3rd trimester, weight triples and length doubles as body stores of protein, fat, iron, and calcium increase.

NEUROLOGIC DEVELOPMENT

During the 3rd wk, a neural plate appears on the ectodermal surface of the trilaminar embryo. Infolding produces a neural tube that will become the central nervous system and a neural crest that will become the peripheral nervous system. Neuroectodermal cells differentiate into neurons, astrocytes, oligodendrocytes, and ependymal cells, whereas microglial cells are derived from mesoderm. By the 5th wk, the 3 main subdivisions of forebrain, midbrain, and hindbrain are evident. The dorsal and ventral horns of the spinal cord have begun to form, along with the peripheral motor and sensory nerves. Myelinization begins at midgestation and continues for years.

By the end of the embryonic period (wk 8), the gross structure of the nervous system has been established. On a cellular level, neurons migrate outward to form the 6 cortical layers. Migration is complete by the 6th mo, but differentiation continues. Axons and dendrites form synaptic connections at a rapid pace, making the central nervous system vulnerable to teratogenic or hypoxic influences throughout gestation. Figure 8-2 shows rates of increase in DNA (a marker of cell number), overall brain weight, and cholesterol (a marker of myelinization). The prenatal and postnatal peaks of DNA probably represent rapid growth of neurons and glia, respectively. By the time of birth, the structure of the brain is complete. Synapses will be pruned back substantially and new connections will be made, largely as a result of experience. Many psychiatric and developmental disorders are thought to result at least in part from disruptions in the **functional connectivity** of brain networks. Disorders of connectivity may begin during fetal life; MRI studies provide a developmental timetable for such connections that lend support to the possible role of disruptions in the establishment of such connections during fetal life.

BEHAVIORAL DEVELOPMENT

No behavioral evidence of neural function is detectable until the 3rd mo. Reflexive responses to tactile stimulation develop in a craniocaudal sequence. By wk 13-14, breathing and swallowing motions appear. The grasp reflex appears at 17 wk and is well developed by 27 wk. Eye

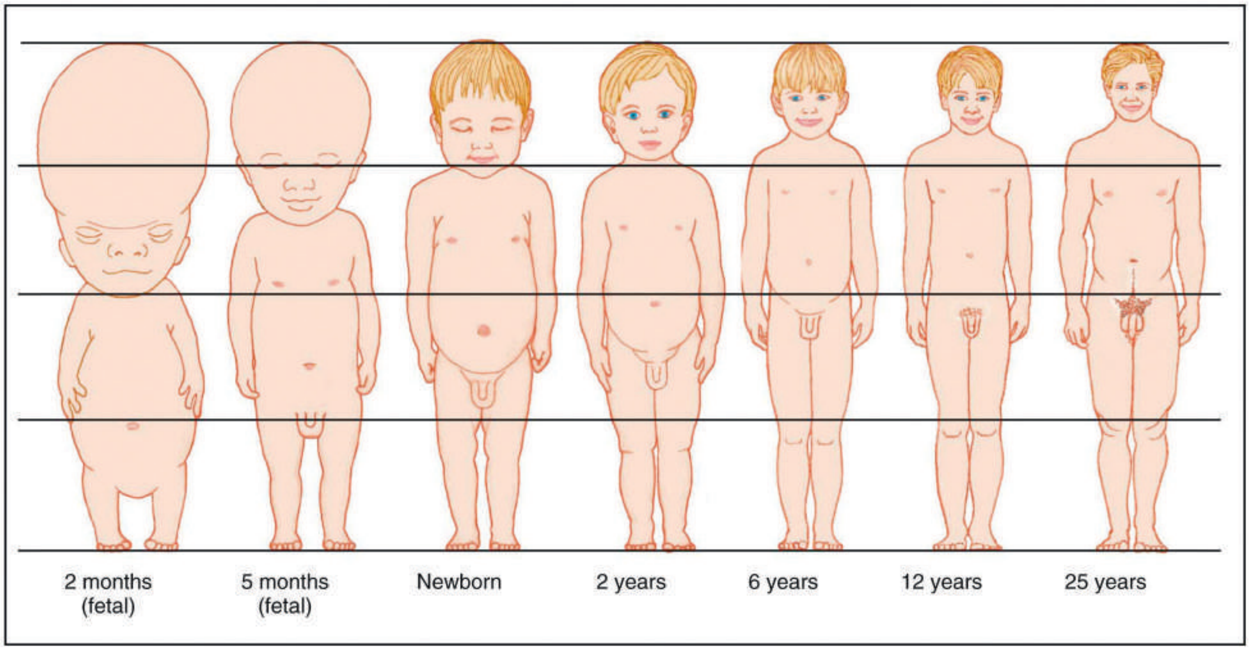

Figure 8-1 Changes in body proportions. Approximate changes in body proportions from fetal life through adulthood are shown. *(From Leifer G:* Introduction to maternity & pediatric nursing, *Philadelphia, 2011, WB Saunders, pp 347–385, Fig. 15-2.)*

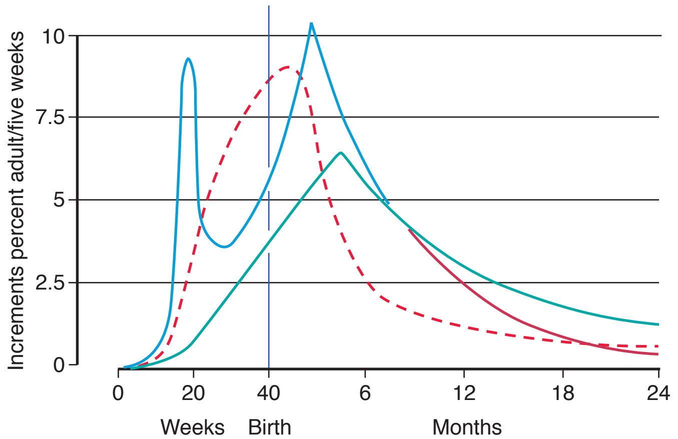

Figure 8-2 Velocity curves of the various components of human brain growth. In Falkner F, Tanner JM, editors:* Human growth: a comprehensive treatise, *New York, 1986, Plenum Press, pp 78–95.)*

opening occurs around 26-28 wk. By midgestation, the full range of neonatal movements can be observed.

During the 3rd trimester, fetuses respond to external stimuli with heart rate elevation and body movements (see Chapter 96). As with infants in the postnatal period, reactivity to auditory (vibroacoustic) and visual (bright light) stimuli vary, depending on their behavioral state, which can be characterized as quiet sleep, active sleep, or awake. Individual differences in the level of fetal activity are commonly noted by mothers and have been observed ultrasonographically. Fetal behavior is affected by maternal medications and diet, increasing after ingestion of caffeine. Behavior may be entrained to the mother's diurnal rhythms: asleep during the day, active at night. Abnormal fetal movement patterns are found in neonates with subsequent muscular or neurologic abnormalities.

Fetal movement increases in response to a sudden auditory tone, but decreases after several repetitions. This demonstrates **habituation,** a basic form of learning in which repeated stimulation results in a response decrement. If the tone changes in pitch, the movement increases again, which is evidence that the fetus distinguishes between a familiar, repeated tone and a novel tone. Habituation improves in older fetuses, and decreases in neurologically impaired or physically stressed fetuses. Similar responses to visual and tactile stimuli have been observed.

PSYCHOLOGIC CHANGES IN PARENTS

Many psychologic changes occur during pregnancy. An unplanned pregnancy may be met with anger, denial, or depression. Ambivalent feelings are the norm, whether or not the pregnancy was planned. Elation at the thought of producing a baby and the wish to be the perfect parent compete with fears of inadequacy and of the lifestyle changes that mothering will impose. Parents of an existing child feel protective for the existing child, worried that the existing child may feel less valued. Old conflicts may resurface as a woman psychologically identifies with her own mother and with herself as a child. The father-to-be faces similar mixed feelings, and problems in the parental relationship may intensify.

Tangible evidence that a fetus exists as a separate being, whether as a result of ultrasonic visualization or awareness of fetal movements (at approximately 20 wk), often heightens a woman's feelings. Parents worry about the fetus's healthy development and mentally rehearse what they will do if the child is malformed, including their response to evidence of abnormality through ultrasound, amniocentesis or other fetal laboratory tests. Toward the end of pregnancy, a woman becomes aware of patterns of fetal activity and reactivity and begins to ascribe to her fetus an individual personality and an ability to survive independently. Appreciation of the psychologic vulnerability of the expectant parents and of the powerful contribution of fetal behavior facilitates supportive clinical intervention.

THREATS TO FETAL DEVELOPMENT

Mortality and morbidity are highest during the prenatal period (see Chapter 93). An estimated 50% of all pregnancies end in spontaneous abortion, including 10-20% of all clinically recognized pregnancies. The vast majority occur in the 1st trimester. Some occur as a result of chromosomal or other abnormalities.

Teratogens associated with gross physical and mental abnormalities include various infectious agents (toxoplasmosis, rubella, syphilis); chemical agents (mercury, thalidomide, antiepileptic medications, and ethanol), high temperature, and radiation (see Chapters 96 and 718).

Teratogenic effects may also result in decreased growth and cognitive or behavioral deficits that only become apparent later in life. Nicotine has vasoconstrictor properties and may disrupt dopaminergic and serotonergic pathways. Prenatal exposure to cigarette smoke is associated with lower birthweight, shorter length, and smaller head circumference, as well as changes in neonatal neurodevelopmental assessments. Later, these children are at increased risk for learning problems, externalizing behavior disorders, and long-term health effects. The effects of prenatal exposure to cocaine, also occurring through alternations in placental blood flow and in direct toxic effects to the developing brain, have been followed in several cohorts and are less dramatic than previously believed. Exposed adolescents show small but significant effects in behavior and functioning, but may not show cognitive impairment. The associated risk factors including other prenatal exposures (alcohol and cigarette co-use) as well as "toxic" postnatal environments frequently characterized by instability, multiple caregivers, and violence exposure remain significant (see Chapters 39 and 40).

The association between an inadequate nutrient supply to the fetus and low birthweight has been recognized for decades; this adaptation on the part of the fetus presumably increases the likelihood that the fetus will survive until birth. For any potential fetal insult, the extent and nature of its effects are determined by characteristics of the host as well as the dose and timing of the exposure. Inherited differences in the metabolism of ethanol, timing of exposure, and the mother's diet may explain the variability in fetal alcohol effects. Organ systems are most vulnerable during periods of maximum growth and differentiation, generally during the 1st trimester (organogenesis). http://www2.epa.gov/children/children-are-not-little-adults details critical periods and specific developmental abnormalities.

Fetal adaptations or responses to an adverse situation in utero (referred to as *fetal programming* or *developmental plasticity*) have lifelong implications for the individual. Fetal programming may prepare the fetus for an environment that matches that experienced in utero. Fetal programming in response to some environmental and nutritional signals in utero increase the risk of cardiovascular disease, diabetes, and obesity in later life. These adverse long-term effects appear to represent a mismatch between fetal and neonatal environmental conditions and the conditions that the individual will confront later in life; a fetus deprived of adequate calories may or may not as a child or teenager face famine. One proposed mechanism for fetal programming is **epigenetic imprinting**, in which two genes are inherited but one is turned off through environmentally induced epigenetic modification (see Chapters 80 and 81.1). Imprinted genes play a critical role in fetal growth and thus may be responsible for the subsequent lifelong effects on growth and related disorders.

Just as the fetal adaptations to the in utero environment may increase the likelihood of later metabolic conditions, the fetus adapts to the mother's psychologic distress. In response to the stressful environment, physiologic changes involving the hypothalamic–pituitary–adrenal axis and the autonomic nervous system occur. Dysregulation of the hypothalamic–pituitary–adrenal axis and autonomic nervous system may explain the associations observed in some but not all studies between maternal distress and negative infant outcomes, including low birthweight, spontaneous abortion, prematurity, and decreased head circumference. In addition, children born to mothers experiencing high stress levels have been found to have higher rates of inattention, impulsivity, conduct disorders, and cognitive changes. Although these changes may have been adaptive in primitive cultures, they are maladaptive in modern societies, leading to psychopathology. Genetic variability, timing of stress during sensitive periods, and the quality of postnatal parenting can attenuate or exacerbate these associations.

Chapter 9

The Newborn

John M. Olsson

(See also Chapter 94.)

Regardless of gestational age, the newborn (neonatal) period begins at birth and includes the 1st mo of life. During this time, marked physiologic transitions occur in all organ systems, and the infant learns to respond to many forms of external stimuli. Because infants thrive physically and psychologically only in the context of their social relationships, any description of the newborn's developmental status has to include consideration of the parents' role as well.

PARENTAL ROLE IN MOTHER–INFANT ATTACHMENT

Parenting a newborn infant requires dedication because a newborn's needs are urgent, continuous, and often unclear. Parents must attend to an infant's signals and respond empathically. Many factors influence parents' ability to assume this role.

Prenatal Factors

Pregnancy is a period of psychologic preparation for the profound demands of parenting. Women may experience ambivalence, particularly (but not exclusively) if the pregnancy was unplanned. If financial worries, physical illness, prior miscarriages or stillbirths, or other crises interfere with psychologic preparation, the neonate may not be welcomed. For adolescent mothers, the demand that they relinquish their own developmental agenda, such as an active social life, may be especially burdensome.

The early experience of being mothered may establish unconsciously held expectations about nurturing relationships that permit mothers to "tune in" to their infants. These expectations are linked with the quality of later infant–parent interactions. Mothers whose early childhoods were marked by traumatic separations, abuse, or neglect may find it especially difficult to provide consistent, responsive care. Instead, they may reenact their childhood experiences with their own infants, as if unable to conceive of the mother–child relationship in any other way. Bonding may be adversely affected by several risk factors during pregnancy and in the postpartum period that undermine the mother–child relationship and may threaten the infant's cognitive and emotional development (Table 9-1).

Social support during pregnancy, particularly support from the father and close family members, is also important. Conversely, conflict with or abandonment by the father during pregnancy may diminish the mother's ability to become absorbed with her infant. Anticipation

Table 9-1 Prenatal Risk Factors for Attachment
Recent death of a loved one
Previous loss of or serious illness in another child
Prior removal of a child
History of depression or serious mental illness
History of infertility or pregnancy loss
Troubled relationship with parents
Financial stress or job loss
Marital discord or poor relationship with the other parent
Recent move or no community ties
No friends or social network
Unwanted pregnancy
No good parenting model
Experience of poor parenting
Drug and/or alcohol abuse
Extreme immaturity

of an early return to work may make some women reluctant to fall in love with their babies because of anticipated separation. Returning to work should be delayed for at least 6 wk, by which time feeding and basic behavioral adjustments have been established.

Many decisions have to be made by parents in anticipation of the birth of their child. One important choice is that of how the infant will be nourished. Among the important benefits of breastfeeding is its promotion of bonding. Providing breastfeeding education for the parents at the prenatal visit by the pediatrician and by the obstetrician during prenatal care can increase maternal confidence in breastfeeding after delivery and reduce stress during the newborn period (see Chapter 45).

Peripartum and Postpartum Influences

The continuous presence during labor of a woman trained to offer friendly support and encouragement (a **doula**) results in shorter labor, fewer obstetric complications (including cesarean section), and reduced postpartum hospital stays. Early skin-to-skin contact between mothers and infants immediately after birth may correlate with an increased rate and longer duration of breastfeeding. Most new parents value even a brief period of uninterrupted time in which to get to know their new infant, and increased mother–infant contact over the 1st days of life may improve long-term mother–child interactions. Nonetheless, early separation, although predictably very stressful, does not inevitably impair a mother's ability to bond with her infant. Early discharge home from the maternity ward may undermine bonding, particularly when a new mother is required to resume full responsibility for a busy household.

Postpartum depression may occur in the 1st wk or up to 6 mo after delivery and can adversely affect neonatal growth and development. Screening methods are available for use during neonatal and infant visits to the pediatric provider (Table 9-2). Referral for care will greatly accelerate recovery.

THE INFANT'S ROLE IN MOTHER–INFANT ATTACHMENT

The in utero environment contributes greatly but not completely to the future growth and development of the fetus. Abnormalities in maternal–fetal placental circulation and maternal glucose metabolism or the presence of maternal infection can result in abnormal fetal growth. Infants may be small or large for gestational age as a result. These abnormal growth patterns not only predispose infants to an increased requirement for medical intervention, but also may affect their ability to respond behaviorally to their parents.

Physical Examination

Examination of the newborn should include an evaluation of growth and an observation of behavior. The average term newborn weighs approximately 3.4 kg (7.5 lb); boys are slightly heavier than girls. Average weight does vary by ethnicity and socioeconomic status. The average length and head circumference are about 50 cm (20 in) and 35 cm (14 in), respectively, in term infants. Each newborn's growth parameters should be plotted on growth curves specific for that infant's gestational age to determine the appropriateness of size. Likewise specific growth charts for conditions associated with variations in growth patterns have also been developed. The infant's response to being examined may be useful in assessing its vigor, alertness, and tone. Observing how the parents handle their infant, their comfort and affection, is also important. The order of the physical examination should be from the least to the most intrusive maneuver. Assessing visual tracking and response to sound and noting changes of tone with level of activity and alertness are very helpful. Performing this examination and sharing impression with parents is an important opportunity to facilitate bonding (see Chapter 94).

Interactional Abilities

Soon after birth, neonates are alert and ready to interact and nurse. This first alert-awake period may be affected by maternal analgesics and anesthetics or fetal hypoxia. Neonates are nearsighted, having a fixed focal length of 8-12 inches, approximately the distance from the breast to the mother's face, as well as an inborn visual preference for faces. Hearing is well developed, and infants preferentially turn toward a female voice. These innate abilities and predilections increase the likelihood that when a mother gazes at her newborn, the baby will gaze back. The initial period of social interaction, usually lasting about 40 minutes, is followed by a period of somnolence. After that, briefer periods of alertness or excitation alternate with sleep. If a mother misses her baby's first alert-awake period, she may not experience as long a period of social interaction for several days. The hypothalamic–midbrain–limbic–paralimbic–cortical circuit of the parents interact to support responses to the infants that are critical for effective parenting (e.g., emotion, attention, motivation, empathy, and decision making).

Modulation of Arousal

Adaptation to extrauterine life requires rapid and profound physiologic changes, including aeration of the lungs, rerouting of the circulation, and activation of the intestinal tract. The necessary behavioral changes are no less profound. To obtain nourishment, to avoid hypo- and hyperthermia, and to ensure safety, neonates must react appropriately to an expanded range of sensory stimuli. Infants must become aroused in response to stimulation, but not so overaroused that their behavior becomes disorganized. Underaroused infants are not able to feed and interact; overaroused infants show signs of **autonomic instability,** including flushing or mottling, perioral pallor, hiccupping, vomiting, uncontrolled limb movements, and inconsolable crying.

Behavioral States

The organization of infant behavior into discrete behavioral states may reflect an infant's inborn ability to regulate arousal. *Six states* have been described: quiet sleep, active sleep, drowsy, alert, fussy, and crying. In the **alert state,** infants visually fixate on objects or faces and follow them horizontally and (within a month) vertically; they also reliably turn toward a novel sound, as if searching for its source. When overstimulated, they may calm themselves by looking away, yawning, or sucking on their lips or hands, thereby increasing parasympathetic activity and reducing sympathetic nervous activity. The behavioral state determines an infant's muscle tone, spontaneous movement, electroencephalogram pattern, and response to stimuli. In **active sleep,** an infant may show progressively less reaction to a repeated heel stick (habituation), whereas in the **drowsy state,** the same stimulus may push a child into fussing or crying.

Mutual Regulation

Parents actively participate in an infant's state regulation, alternately stimulating and soothing. In turn, they are regulated by the infant's signals, responding to cries of hunger with a letdown of milk (or with a bottle). Such interactions constitute a system directed toward furthering the infant's physiologic homeostasis and physical growth. At the same time, they form the basis for the emerging psychologic relationship between parent and child. Infants come to associate the presence of the parent with the pleasurable reduction of tension (as in feeding) and show this preference by calming more quickly for their mother than for a stranger. This response, in turn, strengthens a mother's sense of efficacy and her connection with her baby.

IMPLICATIONS FOR THE PEDIATRICIAN

The pediatrician can support healthy newborn development in several ways.

Optimal Practices

A prenatal pediatric visit allows pediatricians to assess potential threats to bonding (a tense spousal relationship) and sources of social support. Supportive hospital policies include the use of birthing rooms rather than operating suites and delivery rooms; encouragement for the father or a trusted relative or friend to remain with the mother during labor or the provision of a professional doula; the practice of giving the newborn infant to the mother immediately after drying and a brief assessment; placement of the newborn in the mother's room rather

Table 9-2 Edinburgh Postnatal Depression Scale

INSTRUCTIONS FOR USERS

1. The mother is asked to underline the response that comes closest to how she has been feeling in the previous 7 days.
2. All 10 items must be completed.
3. Care should be taken to avoid the possibility of the mother discussing her answers with others.
4. The mother should complete the scale herself, unless she has limited English or has difficulty with reading.
5. The Edinburgh Postnatal Depression Scale may be used at 6-8 wk to screen postnatal women. The child health clinic, a postnatal checkup, or a home visit may provide a suitable opportunity for its completion.

Edinburgh Postnatal Depression Scale

Name:

Address:

Baby's age:

Because you have recently had a baby, we would like to know how you are feeling. Please underline the answer that comes closest to how you have felt in the past 7 days, not just how you feel today.

Here is an example, already completed.

I have felt happy:
- Yes, all the time
- *Yes, most of the time*
- No, not very often
- No, not at all

This would mean: "I have felt happy most of the time" during the past week. Please complete the other questions in the same way.

In the past 7 days:

1. I have been able to laugh and see the funny side of things
   - As much as I always could
   - Not quite so much now
   - Definitely not so much now
   - Not at all
2. I have looked forward with enjoyment to things
   - As much as I ever did
   - Rather less than I used to
   - Definitely less than I used to
   - Hardly at all

*3. I have blamed myself unnecessarily when things went wrong
   - Yes, most of the time
   - Yes, some of the time
   - Not very often
   - No, never

4. I have been anxious or worried for no good reason
   - No, not at all
   - Hardly ever
   - Yes, sometimes
   - Yes, very often

*5. I have felt scared or panicky for no very good reason
   - Yes, quite a lot
   - Yes, sometimes
   - No, not much
   - No, not at all

*6. Things have been getting on top of me
   - Yes, most of the time I haven't been able to cope at all
   - Yes, sometimes I haven't been coping as well as usual
   - No, most of the time I have coped quite well
   - No, I have been coping as well as ever

*7. I have been so unhappy that I have had difficulty sleeping
   - Yes, most of the time
   - Yes, sometimes
   - Not very often
   - No, not at all

*8. I have felt sad or miserable
   - Yes, most of the time
   - Yes, quite often
   - Not very often
   - No, not at all

*9. I have been so unhappy that I have been crying
   - Yes, most of the time
   - Yes, quite often
   - Only occasionally
   - No, never

*10. The thought of harming myself has occurred to me
   - Yes, quite often
   - Sometimes
   - Hardly ever
   - Never

Response categories are scored 0, 1, 2, and 3 according to increased severity of the symptom. Items marked with an asterisk (*) are reverse scored (i.e., 3, 2, 1, and 0). The total score is calculated by adding the scores for each of the 10 items. Users may reproduce the scale without further permission providing they respect copyright (which remains with the *British Journal of Psychiatry*) by quoting the names of the authors, the title, and the source of the paper in all reproduced copies.

From Currie ML, Rademacher R: The pediatrician's role in recognizing and intervening in postpartum depression, Pediatr Clin North Am *51:785–801, 2004.*

than in a central nursery; and avoiding in-hospital distribution of infant formula. Such policies ("Baby Friendly Hospital") have been shown to significantly increase breastfeeding rates (see Chapter 94.3). After discharge, home visits by nurses and lactation counselors can reduce early feeding problems and identify emerging medical conditions in either mother or baby. Infants requiring transport to another hospital should be brought to see the mother first, if at all possible. On discharge home, fathers can shield mothers from unnecessary visits and calls and take over household duties, allowing mothers and infants time to get to know each other without distractions. The first office visit should occur during the 1st 2 wk after discharge to determine how smoothly the mother and infant are making the transition to life at home. Babies who are discharged early, those who are breastfeeding, and those who are at risk for jaundice should be seen 1-3 days after discharge.

Assessing Parent–Infant Interactions

During a feeding or when infants are alert and face-to-face with their parents, it is normal for the dyad to appear absorbed in one another. Infants who become overstimulated by the mother's voice or activity may turn away or close their eyes, leading to a premature termination of the encounter. Alternatively, the infant may be ready to interact, but the mother may appear preoccupied. Asking a new mother about her own emotional state, and inquiring specifically about a history of depression, facilitates referral for therapy, which may provide long-term benefits to the child. Pediatricians may detect **postpartum depression** using the Edinburgh Postnatal Depression Scale at well-child visits during the 1st yr (see Table 9-2).

Teaching About Individual Competencies

The Newborn Behavior Assessment Scale (NBAS) provides a formal measure of an infant's neurodevelopmental competencies, including state control, autonomic reactivity, reflexes, habituation, and orientation toward auditory and visual stimuli. This examination can also be used to demonstrate to parents an infant's capabilities and vulnerabilities. Parents might learn that they need to undress their infant to increase the level of arousal or to swaddle the infant to reduce overstimulation by containing random arm movements. The NBAS can be

used to support the development of positive early parent-infant relationships. Demonstration of the NBAS to parents in the 1st wk of life has been shown to correlate with improvements in the caretaking environment months later.

Chapter 10

The First Year

Susan Feigelman

The prenatal period and the 1st yr of life provide the platform for remarkable growth and development, setting the trajectory for a child's life. Neural plasticity, the ability of the brain to be shaped by experience, both positive and negative, is at its peak. Total brain volume doubles in the 1st yr of life and increases by an additional 15% over the 2nd yr. Total brain volume at age 1 mo is approximately 36% of adult volume but by age 1 yr is approximately 72% (83% by 2 yr) (Fig. 10-1). The acquisition of seemingly "simple" skills, such as swallowing, reflect a series of intricate and highly coordinated processes involving multiple levels of neural control distributed among several physiologic systems whose nature and relationships mature throughout the 1st yr of life. Substantial learning of the basic tools of language (phonology, word segmentation) occurs during infancy. Speech processing in older individuals requires defined and precise neuronal networks; the infant brain possesses a structural and functional organization similar to that of adults, suggesting that structural neurologic processing of speech may guide infants to discover the properties of his or her native language. Myelination of the cortex begins at 7-8 mo gestation and continues into adolescence and young adulthood. It proceeds in a posterior to anterior fashion, allowing progressive maturation of sensory, motor, and finally associative pathways. Given the importance of iron, cholesterol, and other nutrients in myelination, adequate stores throughout infancy are critical (see Chapter 45). Inadequate dietary intake, insufficient interactions with caregivers or the wider environment may alter experience-dependent processes that are critical to brain structure development and function during infancy. Although some of these processes may be delayed, as the periods of plasticity close during the rapid developmental changes occurring in infancy, more permanent deficits may result.

The infant acquires new competences in all developmental domains. The concept of developmental trajectories recognizes that complex skills build on simpler ones; it is also important to realize how development in each domain affects functioning in all of the others. All growth parameters should be plotted using the World Heath Organization charts which show how children from birth through 72 mo "should" grow under optimal circumstances (see Figs. 11-1 and 11-2). Table 10-1 presents an overview of key milestones by domain; Table 10-2 presents similar information arranged by age. Table 10-3 presents age at time of appearance on x-ray of centers of ossification. Parents often

Table 10-1 Developmental Milestones in the 1st 2 Yr of Life

MILESTONE	AVERAGE AGE OF ATTAINMENT (MO)	DEVELOPMENTAL IMPLICATIONS
GROSS MOTOR		
Holds head steady while sitting	2	Allows more visual interaction
Pulls to sit, with no head lag	3	Muscle tone
Brings hands together in midline	3	Self-discovery of hands
Asymmetric tonic neck reflex gone	4	Can inspect hands in midline
Sits without support	6	Increasing exploration
Rolls back to stomach	6.5	Truncal flexion, risk of falls
Walks alone	12	Exploration, control of proximity to parents
Runs	16	Supervision more difficult
FINE MOTOR		
Grasps rattle	3.5	Object use
Reaches for objects	4	Visuomotor coordination
Palmar grasp gone	4	Voluntary release
Transfers object hand to hand	5.5	Comparison of objects
Thumb-finger grasp	8	Able to explore small objects
Turns pages of book	12	Increasing autonomy during book time
Scribbles	13	Visual–motor coordination
Builds tower of 2 cubes	15	Uses objects in combination
Builds tower of 6 cubes	22	Requires visual, gross, and fine motor coordination
COMMUNICATION AND LANGUAGE		
Smiles in response to face, voice	1.5	More active social participant
Monosyllabic babble	6	Experimentation with sound, tactile sense
Inhibits to "no"	7	Response to tone (nonverbal)
Follows one-step command with gesture	7	Nonverbal communication
Follows one-step command without gesture	10	Verbal receptive language (e.g., "Give it to me")
Says "mama" or "dada"	10	Expressive language
Points to objects	10	Interactive communication
Speaks first real word	12	Beginning of labeling
Speaks 4-6 words	15	Acquisition of object and personal names
Speaks 10-15 words	18	Acquisition of object and personal names
Speaks 2-word sentences (e.g., "Mommy shoe")	19	Beginning grammatization, corresponds with 50 word vocabulary
COGNITIVE		
Stares momentarily at spot where object disappeared	2	Lack of object permanence (out of sight, out of mind [e.g., yarn ball dropped])
Stares at own hand	4	Self-discovery, cause and effect
Bangs 2 cubes	8	Active comparison of objects
Uncovers toy (after seeing it hidden)	8	Object permanence
Egocentric symbolic play (e.g., pretends to drink from cup)	12	Beginning symbolic thought
Uses stick to reach toy	17	Able to link actions to solve problems
Pretend play with doll (e.g., gives doll bottle)	17	Symbolic thought

seek information about "normal development" during this period and should be directed to reliable sources, including the American Academy of Pediatrics website (www.AAP.org).

AGE 0-2 MONTHS

In the full-term infant, myelination is present by the time of birth in the dorsal brainstem, cerebellar peduncles, and posterior limb of the internal capsule. The cerebellar white matter acquires myelin by 1 mo of age and is well myelinated by 3 mo of age. The subcortical white matter of the parietal, posterior frontal, temporal, and calcarine cortex is partially myelinated by 3 mo of age. In this period, the infant experiences tremendous growth. Physiologic changes allow the establishment of effective feeding routines and a predictable sleep–wake cycle. The social interactions that occur as parents and infants accomplish these tasks lay the foundation for cognitive and emotional development.

Physical Development

A newborn's weight may initially decrease 10% below birthweight in the 1st wk as a result of excretion of excess extravascular fluid and limited nutritional intake. Nutrition improves as colostrum is replaced by higher-fat breast milk, as infants learn to latch on and suck more efficiently, and as mothers become more comfortable with feeding techniques. Infants regain or exceed birthweight by 2 wk of age and should grow at approximately 30 g (1 oz)/per day during the 1st mo (see Table 15-1). This is the period of fastest postnatal growth. Arms are held to the sides. Limb movements consist largely of uncontrolled writhing, with apparently purposeless opening and closing of the hands. Smiling occurs involuntarily. Eye gaze, head turning, and sucking are under better control and thus can be used to demonstrate infant perception and cognition. An infant's preferential turning toward the mother's voice is evidence of recognition memory.

Six behavioral states have been described (see Chapter 9). Initially, sleep and wakefulness are evenly distributed throughout the 24 hr day (Fig. 10-2). Neurologic maturation accounts for the consolidation of sleep into blocks of 5 or 6 hr at night, with brief awake, feeding periods. Learning also occurs; infants whose parents are consistently more interactive and stimulating during the day learn to concentrate their sleeping during the night.

Cognitive Development

Infants can differentiate among patterns, colors, and consonants. They can recognize facial expressions (smiles) as similar, even when they appear on different faces. They also can match abstract properties of stimuli, such as contour, intensity, or temporal pattern, across sensory modalities. Infants at 2 mo of age can discriminate rhythmic patterns in native vs non-native language. Infants appear to seek stimuli actively,

Table 10-2 Emerging Patterns of Behavior During the 1st Yr of Life*

NEONATAL PERIOD (1ST 4 WK)	
Prone:	Lies in flexed attitude; turns head from side to side; head sags on ventral suspension
Supine:	Generally flexed and a little stiff
Visual:	May fixate face on light in line of vision; "doll's-eye" movement of eyes on turning of the body
Reflex:	Moro response active; stepping and placing reflexes; grasp reflex active
Social:	Visual preference for human face
AT 1 MO	
Prone:	Legs more extended; holds chin up; turns head; head lifted momentarily to plane of body on ventral suspension
Supine:	Tonic neck posture predominates; supple and relaxed; head lags when pulled to sitting position
Visual:	Watches person; follows moving object
Social:	Body movements in cadence with voice of other in social contact; beginning to smile
AT 2 MO	
Prone:	Raises head slightly farther; head sustained in plane of body on ventral suspension
Supine:	Tonic neck posture predominates; head lags when pulled to sitting position
Visual:	Follows moving object 180 degrees
Social:	Smiles on social contact; listens to voice and coos
AT 3 MO	
Prone:	Lifts head and chest with arms extended; head above plane of body on ventral suspension
Supine:	Tonic neck posture predominates; reaches toward and misses objects; waves at toy
Sitting:	Head lag partially compensated when pulled to sitting position; early head control with bobbing motion; back rounded
Reflex:	Typical Moro response has not persisted; makes defensive movements or selective withdrawal reactions
Social:	Sustained social contact; listens to music; says "aah, ngah"
AT 4 MO	
Prone:	Lifts head and chest, with head in approximately vertical axis; legs extended
Supine:	Symmetric posture predominates, hands in midline; reaches and grasps objects and brings them to mouth
Sitting:	No head lag when pulled to sitting position; head steady, tipped forward; enjoys sitting with full truncal support
Standing:	When held erect, pushes with feet
Adaptive:	Sees raisin, but makes no move to reach for it
Social:	Laughs out loud; may show displeasure if social contact is broken; excited at sight of food
AT 7 MO	
Prone:	Rolls over; pivots; crawls or creep-crawls (Knobloch)
Supine:	Lifts head; rolls over; squirms
Sitting:	Sits briefly, with support of pelvis; leans forward on hands; back rounded
Standing:	May support most of weight; bounces actively
Adaptive:	Reaches out for and grasps large object; transfers objects from hand to hand; grasp uses radial palm; rakes at raisin
Language:	Forms polysyllabic vowel sounds
Social:	Prefers mother; babbles; enjoys mirror; responds to changes in emotional content of social contact
AT 10 MO	
Sitting:	Sits up alone and indefinitely without support, with back straight
Standing:	Pulls to standing position; "cruises" or walks holding on to furniture
Motor:	Creeps or crawls
Adaptive:	Grasps objects with thumb and forefinger; pokes at things with forefinger; picks up pellet with assisted pincer movement; uncovers hidden toy; attempts to retrieve dropped object; releases object grasped by other person
Language:	Repetitive consonant sounds ("mama," "dada")
Social:	Responds to sound of name; plays peek-a-boo or pat-a-cake; waves bye-bye
AT 1 YR	
Motor:	Walks with one hand held; rises independently, takes several steps (Knobloch)
Adaptive:	Picks up raisin with unassisted pincer movement of forefinger and thumb; releases object to other person on request or gesture
Language:	Says a few words besides "mama," "dada"
Social:	Plays simple ball game; makes postural adjustment to dressing

*Data are derived from those of Gesell (as revised by Knobloch), Shirley, Provence, Wolf, Bailey, and others.
Data from Knobloch H, Stevens F, Malone AF: Manual of developmental diagnosis, *Hagerstown, MD, 1980, Harper & Row.*

as though satisfying an innate need to make sense of the world. These phenomena point to the integration of sensory inputs in the central nervous system. Caretaking activities provide visual, tactile, olfactory, and auditory stimuli; all of these support the development of cognition. Infants habituate to the familiar, attending less to repeated stimuli and increasing their attention to novel stimuli.

Emotional Development

The infant is dependent on the environment to meet his or her needs. The consistent availability of a trusted adult to meet the infant's urgent needs creates the conditions for secure attachment. Basic trust vs mistrust, the first of Erikson's psychosocial stages (see Chapter 6), depends on attachment and reciprocal maternal bonding. Crying occurs in response to stimuli that may be obvious (a soiled diaper), but are often obscure. Infants who are consistently picked up and held in response to distress cry less at 1 yr and show less-aggressive behavior at 2 yr. Cross-cultural studies show that in societies in which infants are carried close to the mother, babies cry less than in societies in which babies are only periodically carried. Crying normally peaks at about 6 wk of age, when healthy infants may cry up to 3 hr/day, then decreases to 1 hr or less by 3 mo. Infants cry in response to the cry of another infant, which has been interpreted as an early sign of empathy development.

Crying/fussiness is present in 20% of infants younger than 2 mo of age and although in most it is a transient and normal behavioral activity, it is often associated with parental concern and distress. Excessive

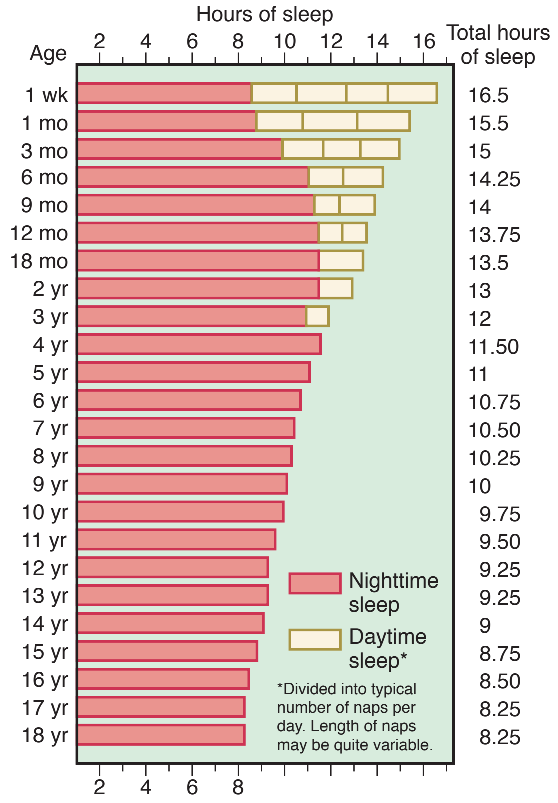

Figure 10-2 Typical sleep requirements in children. *(From Ferber R: Solve your child's sleep problems, New York, 1985, Simon & Schuster.)*

crying (longer than 3 hr/day, longer than 3 days/wk lasting longer than 1 wk) and more often crying/fussiness persisting longer than 3-5 mo might be associated with child abuse, behavioral problems when an older child (anxiety, aggression, hyperactivity), decreased duration of breastfeeding and postnatal depression (uncertain which is the cause or effect). Most infants with crying/fussiness do not have gastroesophageal reflux, lactose intolerance, or cow-milk protein allergy. Some researchers believe excessive crying may be an early manifestation of migraines.

Infants have various signals for their needs and for getting attention from a caregiver. These behaviors progressively increase in intensity in many infants from changes in breathing and color, to postural and movement cures, and then to calm vocalizations. These precry cues, if not attended to, will eventually lead to active crying. Some infants may go directly to crying, perhaps based on temperament; these infants may be less easily consolable and may have feeding problems like refusal of feeds. Sensory integration issues may also be involved with the child being over responsive or sensory deprived.

Management of crying/fussiness should include teaching caregivers about precry cues and responding to the signal for feeding in a calm relaxed manner. If sensory overstimulation is a factor, creating a nondistracting, calm environment may help as well as swaddling. When lack of sensory stimulation is present, mother–infant skin-to-skin contact, and carrying the infant may be beneficial. In all situations, reassurance that this is both normal and transient, with only 5% of infants persisting beyond 3 mo of age, helps the family cope.

The emotional significance of any experience depends on both the individual child's temperament and the parent's responses (see Table 6-1); differing feeding schedules produce differing reactions. Hunger generates increasing tension; as the urgency peaks, the infant cries, the parent offers the breast or bottle and the tension dissipates. Infants fed "on demand" consistently experience this link between their distress, the arrival of the parent, and relief from hunger. Most infants fed on a fixed schedule quickly adapt their hunger cycle to the schedule. Those who cannot because they are temperamentally prone to irregular biologic rhythms experience periods of unrelieved hunger as well as unwanted feedings when they already feel full. Similarly, infants who are fed at the parents' convenience, with neither attention to the infant's hunger cues nor a fixed schedule, may not consistently experience feeding as the pleasurable reduction of tension. Infants with early dysregulation often show increased irritability and physiologic instability (spitting, diarrhea, poor weight gain) as well as later behavioral problems.

Implications for Parents and Pediatricians

Success or failure in establishing feeding and sleep cycles determines parents' feelings of efficacy. When things go well, the parents' anxiety and ambivalence, as well as the exhaustion of the early weeks, decrease. Infant issues (colic) or familial conflict will prevent this from occurring. With physical recovery from delivery and hormonal normalization, the mild postpartum depression that affects many mothers passes. If the mother continues to feel sad, overwhelmed, and anxious, the possibility of moderate to severe postpartum depression, found in 10-15% of postpartum women, needs to be considered. Major **depression** that arises during pregnancy or in the postpartum period threatens the mother–child relationship and is a risk factor for later cognitive and behavioral problems. The pediatrician may be the first professional to encounter the depressed mother and should be instrumental in assisting her in seeking treatment (see Chapter 9).

AGE 2-6 MONTHS

At about age 2 mo, the emergence of voluntary (social) smiles and increasing eye contact mark a change in the parent–child relationship, heightening the parents' sense of being loved reciprocally. During the next months, an infant's range of motor and social control and cognitive engagement increases dramatically. Mutual regulation takes the form of complex social interchanges, resulting in strong mutual attachment and enjoyment. Routines are established. Parents are less fatigued.

Physical Development

Between 3 and 4 mo of age, the rate of growth slows to approximately 20 g/day (see Table 15-1 and Figs. 11-1 and 11-2). By age 4 mo, birth weight is doubled. Early reflexes that limited voluntary movement recede. Disappearance of the asymmetric tonic neck reflex means that infants can begin to examine objects in the midline and manipulate them with both hands (see Chapter 590). Waning of the early grasp reflex allows infants both to hold objects and to let them go voluntarily. A novel object may elicit purposeful, although inefficient, reaching. The quality of spontaneous movements also changes, from larger writhing to smaller, circular movements that have been described as "fidgety." Abnormal or absent fidgety movements may constitute a risk factor for later neurologic abnormalities.

Increasing control of truncal flexion makes intentional rolling possible. Once infants can hold their heads steady while sitting, they can gaze across at things rather than merely looking up at them, opening up a new visual range. They can begin taking food from a spoon. At the same time, maturation of the visual system allows greater depth perception.

In this period, infants achieve stable state regulation and regular sleep–wake cycles. Total sleep requirements are approximately 14-16 hr/24 hr, with about 9-10 hr concentrated at night and 2 naps/day. Approximately 70% of infants sleep for a 6-8 hr stretch by age 6 mo (see Fig. 10-2). By 4-6 mo, the sleep electroencephalogram shows a mature pattern, with demarcation of rapid eye movement and 4 stages of non–rapid eye movement sleep. The sleep cycle remains shorter than in adults (50-60 min vs approximately 90 min). As a result, infants arouse to light sleep or wake frequently during the night, setting the stage for behavioral sleep problems (see Chapter 19).

Cognitive Development

The overall effect of these developments is a qualitative change. At 4 mo of age, infants are described as "hatching" socially, becoming interested in a wider world. During feeding, infants no longer focus exclusively on the mother, but become distracted. In the mother's arms, the infant may literally turn around, preferring to face outward.

Infants at this age also explore their own bodies, staring intently at their hands, vocalizing, blowing bubbles, and touching their ears, cheeks, and genitals. These explorations represent an early stage in the understanding of cause and effect as infants learn that voluntary muscle movements generate predictable tactile and visual sensations. They also have a role in the emergence of a sense of self, separate from the mother. This is the 1st stage of personality development. Infants come to associate certain sensations through frequent repetition. The proprioceptive feeling of holding up the hand and wiggling the fingers always accompanies the sight of the fingers moving. Such self sensations are consistently linked and reproducible at will. In contrast, sensations that are associated with "other" occur with less regularity and in varying combinations. The sound, smell, and feel of the mother sometimes appear promptly in response to crying, but sometimes do not. The satisfaction that the mother or another loving adult provides continues the process of attachment.

Emotional Development and Communication

Babies interact with increasing sophistication and range. The primary emotions of anger, joy, interest, fear, disgust, and surprise appear in appropriate contexts as distinct facial expressions. When face-to-face, the infant and a trusted adult can match affective expressions (smiling or surprise) approximately 30% of the time. Initiating games (singing, hand games) increases social development. Such face-to-face behavior reveals the infant's ability to share emotional states, the 1st step in the development of communication. Infants of depressed parents show a different pattern, spending less time in coordinated movement with their parents and making fewer efforts to reengage. Rather than anger, they show sadness and a loss of energy when the parents continue to be unavailable.

Implications for Parents and Pediatricians

Motor and sensory maturation makes infants at 3-6 mo exciting and interactive. Some parents experience their 4 mo old child's outward turning as a rejection, secretly fearing that their infants no longer love them. For most parents, this is a happy period. Most parents excitedly report that they can hold conversations with their infants, taking turns vocalizing and listening. Pediatricians share in the enjoyment, as the baby coos, makes eye contact, and moves rhythmically. Infants who do not show this reciprocal language and movements are at risk for autism spectrum disorders (see Chapter 30). If this visit does not feel joyful and relaxed, causes such as social stress, family dysfunction, parental mental illness, or problems in the infant–parent relationship should be considered. Parents can be reassured that responding to an infant's emotional needs cannot spoil the infant. Giving vaccines and drawing blood while the child is seated on the parent's lap or nursing at the breast increases pain tolerance.

AGE 6-12 MONTHS

With achievement of the sitting position, increased mobility, and new skills to explore the world around them, 6-12 mo old infants show advances in cognitive understanding and communication, and there are new tensions around the themes of attachment and separation. Infants develop will and intentions, characteristics that most parents welcome, but still find challenging to manage.

Physical Development

Growth slows more (see Table 15-1 and Figs. 11-1 and 11-2). By the 1st birthday, birth weight has tripled, length has increased by 50%, and head circumference has increased by 10 cm. The ability to sit unsupported (6-7 mo) and to pivot while sitting (around 9-10 mo) provides increasing opportunities to manipulate several objects at a time and to experiment with novel combinations of objects. These explorations are aided by the emergence of a thumb–finger grasp (8-9 mo) and a neat pincer grasp by 12 mo. Voluntary release emerges at 9 mo. Many infants begin crawling and pulling to stand around 8 mo, followed by cruising. Some walk by 1 yr. Motor achievements correlate with increasing myelinization and cerebellar growth. These gross motor skills expand infants' exploratory range and create new physical dangers, as well as opportunities for learning. Tooth eruption occurs, usually starting with the mandibular central incisors. Tooth development reflects skeletal maturation and bone age, although there is wide individual variation (see Table 10-3 and Chapter 307).

Cognitive Development

The 6 mo old infant has discovered his hands and will soon learn to manipulate objects. At first, everything is mouthed. In time, novel

objects are picked up, inspected, passed from hand to hand, banged, dropped, and then mouthed. Each action represents a nonverbal idea about what things are for (in Piagetian terms, a *schema;* see Chapter 6). The complexity of an infant's play, how many different schemata are brought to bear, is a useful index of cognitive development at this age. The pleasure, persistence, and energy with which infants tackle these challenges suggest the existence of an intrinsic drive or mastery motivation. Mastery behavior occurs when infants feel secure; those with less secure attachments show limited experimentation and less competence.

A major milestone is the achievement by 9 mo of **object permanence** (**constancy**), the understanding that objects continue to exist, even when not seen. At 4-7 mo of age, infants look down for a yarn ball that has been dropped but quickly give up if it is not seen. With object constancy, infants persist in searching. They will find objects hidden under a cloth or behind the examiner's back. Peek-a-boo brings unlimited pleasure as the child magically brings back the other player. Events seem to occur as a result of the child's own activities.

Emotional Development

The advent of object permanence corresponds with qualitative changes in social and communicative development. Infants look back and forth between an approaching stranger and a parent, and may cling or cry anxiously, demonstrating **stranger anxiety**. Separations often become more difficult. Infants who have been sleeping through the night for mo begin to awaken regularly and cry, as though remembering that the parents are in the next room.

A new demand for autonomy also emerges. Poor weight gain at this age often reflects a struggle between an infant's emerging independence and parent's control of the feeding situation. Use of the 2-spoon method of feeding (1 for the child and 1 for the parent), finger foods, and a high chair with tray table can avert potential problems. Tantrums make their first appearance as the drives for autonomy and mastery come in conflict with parental controls and the infants' still-limited abilities.

Communication

Infants at 7 mo of age are adept at nonverbal communication, expressing a range of emotions and responding to vocal tone and facial expressions. Around 9 mo of age, infants become aware that emotions can be shared between people; they show parents toys as a way of sharing their happy feelings. Between 8 and 10 mo of age, babbling takes on a new complexity, with multisyllabic sounds ("ba-da-ma"); babies can discriminate between languages. Infants in bilingual homes learn the characteristics and rules that govern 2 different languages. Social interaction (attentive adults taking turns vocalizing with the infant) profoundly influences the acquisition and production of new sounds. The first true word (i.e., a sound used consistently to refer to a specific object or person) appears in concert with an infant's discovery of object permanence. Picture books now provide an ideal context for verbal language acquisition. With a familiar book as a shared focus of attention, a parent and child engage in repeated cycles of pointing and labeling, with elaboration and feedback by the parent. The addition of sign language may support infant development while enhancing mother–infant communication.

Implications for Parents and Pediatricians

With the developmental reorganization that occurs around 9 mo of age, previously resolved issues of feeding and sleeping reemerge. Pediatricians can prepare parents at the 6 mo visit so that these problems can be understood as the result of developmental progress and not regression. Parents should be encouraged to plan ahead for necessary, and inevitable, separations (e.g., babysitter, daycare). Routine preparations may make these separations easier. Although controversial, the stability that comes with dual parent employment may be beneficial for long-term social emotional outcomes. Introduction of a **transitional object** may allow the infant to self-comfort in the parents' absence. The object cannot have any potential for asphyxiation or strangulation.

Infants' wariness of strangers often makes the 9 mo examination difficult, particularly if the infant is temperamentally prone to react negatively to unfamiliar situations. Initially, the pediatrician should avoid direct eye contact with the child. Time spent talking with the parent and introducing the child to a small, washable toy will be rewarded with more cooperation. The examination can be continued on the parent's lap when feasible.

Chapter 11

The Second Year

Susan Feigelman

The toddler's newly found ability to walk allows separation and independence; however, the toddler continues to need secure attachment to the parents. At approximately 18 mo of age, the emergence of symbolic thought and language causes a reorganization of behavior, with implications across many developmental domains.

AGE 12-18 MONTHS

Physical Development

The toddler continues to experience considerable brain growth and myelination in the 2nd yr, resulting in an increase in head circumference of 2 cm over the year (Fig. 11-1; see also Fig. 10-1). Toddlers have relatively short legs and long torsos, with exaggerated lumbar lordosis and protruding abdomens. Growth in length continues at a steady rate (Fig. 11-2).

Most children begin to walk independently at around 12-15 mo of age. Early walking is not associated with advanced development in other domains. Infants initially toddle with a wide-based gait, with the knees bent and the arms flexed at the elbow; the entire torso rotates with each stride; the toes may point in or out, and the feet strike the floor flat. The appearance is that of genu varus (bowleg). Subsequent refinement leads to greater steadiness and energy efficiency. After several months of practice, the center of gravity shifts back and the torso stabilizes, while the knees extend and the arms swing at the sides for balance. The feet are held in better alignment, and the child is able to stop, pivot, and stoop without toppling over (see Chapters 672 and 673).

Cognitive Development

Exploration of the environment increases in parallel with improved dexterity (reaching, grasping, releasing) and mobility. Learning follows the precepts of Piaget's sensorimotor stage (see Chapter 6). Toddlers manipulate objects in novel ways to create interesting effects, such as stacking blocks or putting things into a computer disk drive. Playthings are also more likely to be used for their intended purposes (combs for hair, cups for drinking). Imitation of parents and older siblings or other children is an important mode of learning. Make-believe (symbolic) play centers on the child's own body (pretending to drink from an empty cup) (Table 11-1; also see Table 10-1).

Emotional Development

Infants who are approaching the developmental milestone of taking their first steps may be irritable. Once they start walking, their predominant mood changes markedly. Toddlers are described as "intoxicated" or "giddy" with their new ability and with the power to control the distance between themselves and their parents. Exploring toddlers orbit around their parents, moving away and then returning for a reassuring touch before moving away again. A securely attached child will

Table 11-1 Emerging Patterns of Behavior from 1-5 Yr of Age*

Age/Domain	Behavior
15 MO	
Motor:	Walks alone; crawls up stairs
Adaptive:	Makes tower of 3 cubes; makes a line with crayon; inserts raisin in bottle
Language:	Jargon; follows simple commands; may name a familiar object (e.g., ball); responds to his/her name
Social:	Indicates some desires or needs by pointing; hugs parents
18 MO	
Motor:	Runs stiffly; sits on small chair; walks up stairs with 1 hand held; explores drawers and wastebaskets
Adaptive:	Makes tower of 4 cubes; imitates scribbling; imitates vertical stroke; dumps raisin from bottle
Language:	10 words (average); names pictures; identifies 1 or more parts of body
Social:	Feeds self; seeks help when in trouble; may complain when wet or soiled; kisses parent with pucker
24 MO	
Motor:	Runs well, walks up and down stairs, 1 step at a time; opens doors; climbs on furniture; jumps
Adaptive:	Makes tower of 7 cubes (6 at 21 mo); scribbles in circular pattern; imitates horizontal stroke; folds paper once imitatively
Language:	Puts 3 words together (subject, verb, object)
Social:	Handles spoon well; often tells about immediate experiences; helps to undress; listens to stories when shown pictures
30 MO	
Motor:	Goes up stairs alternating feet
Adaptive:	Makes tower of 9 cubes; makes vertical and horizontal strokes, but generally will not join them to make cross; imitates circular stroke, forming closed figure
Language:	Refers to self by pronoun "I"; knows full name
Social:	Helps put things away; pretends in play
36 MO	
Motor:	Rides tricycle; stands momentarily on 1 foot
Adaptive:	Makes tower of 10 cubes; imitates construction of "bridge" of 3 cubes; copies circle; imitates cross
Language:	Knows age and sex; counts 3 objects correctly; repeats 3 numbers or a sentence of 6 syllables; most of speech intelligible to strangers
Social:	Plays simple games (in "parallel" with other children); helps in dressing (unbuttons clothing and puts on shoes); washes hands
48 MO	
Motor:	Hops on 1 foot; throws ball overhand; uses scissors to cut out pictures; climbs well
Adaptive:	Copies bridge from model; imitates construction of "gate" of 5 cubes; copies cross and square; draws man with 2-4 parts besides head; identifies longer of 2 lines
Language:	Counts 4 pennies accurately; tells story
Social:	Plays with several children, with beginning of social interaction and role-playing; goes to toilet alone
60 MO	
Motor:	Skips
Adaptive:	Draws triangle from copy; names heavier of 2 weights
Language:	Names 4 colors; repeats sentence of 10 syllables; counts 10 pennies correctly
Social:	Dresses and undresses; asks questions about meaning of words; engages in domestic role-playing

*Data derived from those of Gesell (as revised by Knobloch), Shirley, Provence, Wolf, Bailey, and others. After 6 yr, the Wechsler Intelligence Scales for Children (WISC-IV) and other scales offer the most precise estimates of developmental level. To have their greatest value, they should be administered only by an experienced and qualified person.

use the parent as a secure base from which to explore independently. Proud of her or his accomplishments, the child illustrates Erikson's stage of autonomy and separation (see Chapter 6). The toddler who is overly controlled and discouraged from active exploration will feel doubt, shame, anger, and insecurity. All children will experience tantrums, reflecting their inability to delay gratification, suppress or displace anger, or verbally communicate their emotional states. The quality of the parent–child relationship may moderate negative effects of childcare arrangements when parents work.

Linguistic Development

Receptive language precedes expressive language. By the time infants speak their first words around 12 mo of age, they already respond appropriately to several simple statements, such as "no," "bye-bye," and "give me." By 15 mo, the average child points to major body parts and uses 4-6 words spontaneously and correctly. Toddlers also enjoy **polysyllabic** jargoning (see Tables 10-1 and 11-1), but do not seem upset that no one understands. Most communication of wants and ideas continues to be nonverbal.

Implications for Parents and Pediatricians

Parents who cannot recall any other milestone tend to remember when their child began to walk, perhaps because of the symbolic significance of walking as an act of independence and/or because of the new demands that the ambulating toddler places on his or her parent. All toddlers should be encouraged to explore their environments; a child's ability to wander out of sight also increases the risks of injury and the need for supervision.

In the office setting, many toddlers are comfortable exploring the examination room, but cling to the parents under the stress of the examination. Performing most of the physical examination in the parent's lap may help allay fears of separation. Infants who become more, not less, distressed in their parents' arms or who avoid their parents at times of stress may be insecurely attached. Young children who, when distressed, turn to strangers rather than parents for comfort are particularly worrisome. Children raised in "toxic" stressful environments have increased vulnerability to disease. The conflicts between independence and security manifest in issues of discipline, temper tantrums, toilet training, and changing feeding behaviors. Parents should be counseled on these matters within the framework of normal development.

Parents may express concern about poor food intake as growth slows. The growth chart should provide reassurance. Most children still take two daytime naps, although the duration steadily decreases (see Fig. 10-1).

AGE 18-24 MONTHS

Physical Development

Motor development during this period is reflected in improvements in balance and agility and the emergence of running and stair climbing. Height and weight increase at a steady rate during this year, with a gain of 5 in and 5 lb. By 24 mo, children are about half of their ultimate adult height. Head growth slows slightly. Eighty-five percent of adult head circumference is achieved by age 2 yr, with just an additional 5 cm gain over the next few years (see Fig. 11-1 and Table 15-1).

Cognitive Development

At approximately 18 mo of age, several cognitive changes coalesce, marking the conclusion of the sensory-motor period. These can be observed during self-initiated play. *Object permanence* is firmly established; toddlers anticipate where an object will end up, even though the object was not visible while it was being moved. *Cause and effect* are better understood, and toddlers demonstrate flexibility in problem solving (e.g., using a stick to obtain a toy that is out of reach, figuring out how to wind a mechanical toy). *Symbolic transformations* in play are no longer tied to the toddler's own body, so that a doll can be "fed" from an empty plate. Like the reorganization that occurs at 9 mo (see Chapter 10), the cognitive changes at 18 mo correlate with important changes in the emotional and linguistic domains (see Table 11-1).

Emotional Development

The relative independence of the preceding half-year often gives way to increased clinginess around 18 mo. This stage, described as "rapprochement," may be a reaction to growing awareness of the possibility of separation. Many parents report that they cannot go anywhere without having a small child attached to them. **Separation anxiety** will be manifest at bedtime. Many children use a special blanket or stuffed toy as a **transitional object,** which functions as a symbol of the absent parent. The transitional object remains important until the transition to symbolic thought has been completed and the symbolic presence of the parent has been fully internalized. Despite the attachment to the parent, the child's use of "no" is a way of declaring independence. Individual differences in temperament, in both the child and the parents play a critical role in determining the balance of conflict vs cooperation in the parent–child relationship. As effective language emerges, conflicts become less frequent.

Self-conscious awareness and internalized standards of behavior first appear at this age. Toddlers looking in a mirror will, for the first time, reach for their own face rather than the mirror image if they notice something unusual on their nose. They begin to recognize when toys are broken and may hand them to their parents to fix. Language becomes a means of impulse control, early reasoning, and connection between ideas. When tempted to touch a forbidden object, they may tell themselves "no, no." This is the very beginning of the formation of a conscience. The fact that they often go on to touch the object anyway demonstrates the relative weakness of internalized inhibitions at this stage.

Linguistic Development

Perhaps the most dramatic developments in this period are linguistic. Labeling of objects coincides with the advent of symbolic thought. After the realization that words can stand for things occurs, a child's vocabulary balloons from 10-15 words at 18 mo to between 50 and 100 at 2 yr. After acquiring a vocabulary of about 50 words, toddlers begin to combine them to make simple sentences, the beginning of grammar. At this stage, toddlers understand **2-step commands,** such as "Give me the ball and then get your shoes." Language also gives the toddler a sense of control over the surroundings, as in "night-night" or "bye-bye." The emergence of verbal language marks the end of the sensory-motor period. As toddlers learn to use symbols to express ideas and solve problems, the need for cognition based on direct sensation and motor manipulation wanes.

Implications for Parents and Pediatricians

With children's increasing mobility, physical limits on their explorations become less effective; words become increasingly important for behavior control as well as cognition. Children with delayed language acquisition often have greater behavior problems and frustrations due to problems with communication. Language development is facilitated when parents and caregivers use clear, simple sentences; ask questions; and respond to children's incomplete sentences and gestural communication with the appropriate words. Television viewing, as well as television as background noise, decreases parent–child verbal interactions, whereas looking at picture books and engaging the child in 2-way conversations stimulate language development.

In the office setting, certain procedures may lessen the child's **stranger anxiety.** Avoid direct eye contact initially. Perform as much of the examination as feasible with the child on the parent's lap. Pediatricians can help parents understand the resurgence of problems with separation and the appearance of a treasured blanket or teddy bear as a developmental phenomenon. Parents must understand the importance of exploration. Rather than limiting movement, parents should place toddlers in safe environments or substitute 1 activity for another. Methods of discipline, including corporal punishment, should be discussed; effective alternatives will usually be appreciated. Helping parents to understand and adapt to their children's different temperamental styles can constitute an important intervention (see Table 6-1). Developing daily routines is helpful to all children at this age. Rigidity in those routines reflects a need for mastery over a changing environment.

Chapter 12

The Preschool Years

Susan Feigelman

The emergence of language and exposure of children to an expanding social sphere represent the critical milestones for children ages 2-5 yr. As toddlers, children learn to walk away and come back to the secure adult or parent. As preschoolers, they explore emotional separation, alternating between stubborn opposition and cheerful compliance, between bold exploration and clinging dependence. Increasing time spent in classrooms and playgrounds challenges a child's ability to adapt to new rules and relationships. Emboldened by their growing array of new skills and accomplishments, preschool children also are increasingly cognizant of the constraints imposed on them by the adult world and their own limited abilities.

STRUCTURAL DEVELOPMENT OF THE BRAIN

The preschool brain experiences dramatic changes in its anatomical and physiologic characteristics, with increases in cortical area, decreases in cortical thickness, and changing cortical volume. These changes are not uniform across the brain, but vary by region. Gray and white matter tissue properties change dramatically, including diffusion properties in the major cerebral fiber tracts. Dramatic increases occur in the brain metabolic demands. In general, a greater number of brain regions are required among younger compared to older children to complete the same cognitive task. This duplication has been interpreted as a form of "scaffolding," which is discarded with increasing age. The preschool brain is characterized by growth and expansion, that will be followed in later years by pruning.

PHYSICAL DEVELOPMENT

Somatic and brain growth slows by the end of the 2nd yr of life, with corresponding decreases in nutritional requirements and appetite, and the emergence of "picky" eating habits (see Table 15-1). Increases of approximately 2 kg (4-5 lb) in weight and 7-8 cm (2-3 in) in height per year are expected. Birthweight quadruples by 2.5 yr of age. An average 4 yr old weighs 40 lb and is 40 in tall. The head will grow only an additional 5-6 cm between ages 3 and 18 yr. Current growth charts, with growth parameters, can be found on the Centers for Disease Control and Prevention website (http://www.cdc.gov/growthcharts/) and in Chapter 15. Children with early adiposity rebound (increase in body mass index) are at increased risk for adult obesity.

Growth of sexual organs is commensurate with somatic growth. The preschooler has genu valgum (knock-knees) and mild pes planus (flatfoot). The torso slims as the legs lengthen. Physical energy peaks, and the need for sleep declines to 11-13 hr/24 hr, with the child eventually dropping the nap (see Fig. 10-1). Visual acuity reaches 20/30 by age 3 yr and 20/20 by age 4 yr. All 20 primary teeth have erupted by 3 yr of age (see Chapter 307).

Most children walk with a mature gait and run steadily before the end of their 3rd yr (see Table 11-1). Beyond this basic level, there is wide variation in ability as the range of motor activities expands to include throwing, catching, and kicking balls; riding on bicycles; climbing on playground structures; dancing; and other complex pattern behaviors. Stylistic features of gross motor activity, such as

tempo, intensity, and cautiousness, also vary significantly. Although toddlers may walk with different styles, toe walking should not persist.

The effects of such individual differences on cognitive and emotional development depend in part on the demands of the social environment. Energetic, coordinated children may thrive emotionally with parents or teachers who encourage physical activity; lower-energy, more cerebral children may thrive with adults who value quiet play.

Handedness is usually established by the 3rd yr. Frustration may result from attempts to change children's hand preference. Variations in fine-motor development reflect both individual proclivities and different opportunities for learning. Children who are restricted from drawing with crayons, for example, develop a mature pencil grasp later.

Bowel and bladder control emerge during this period, with "readiness" for toileting having large individual and cultural variation. Girls tend to train faster and earlier than boys. Bed-wetting is normal up to age 4 yr in girls and age 5 yr in boys (see Chapter 23.3). Many children master toileting with ease, particularly once they are able to verbalize their bodily needs. For others, toilet training can involve a protracted power struggle. Refusal to defecate in the toilet or potty is relatively common and can lead to constipation and parental frustration. Defusing the issue with a temporary cessation of training (and a return to diapers) often allows toilet mastery to proceed.

Implications for Parents and Pediatricians

The normal decrease in appetite at this age may cause parental concern about nutrition; growth charts should reassure parents that the child's intake is adequate. Children normally modulate their food intake to match their somatic needs according to feelings of hunger and satiety. Daily intake fluctuates, at times widely, but intake during the period of a week is relatively stable. A complete multivitamin can be used to assure adequate vitamin and mineral intake. Parents should provide a predictable eating schedule, with 3 meals and 2 snacks per day, allowing the child to choose how much to eat.

Highly active children face increased risks of injury, and parents should be counseled about safety precautions. Parental concerns about possible hyperactivity may reflect inappropriate expectations, heightened fears, or true overactivity. Children who engage in impulsive activity with no apparent regard for personal safety should be evaluated further.

LANGUAGE, COGNITION, AND PLAY

These 3 domains all involve symbolic function, a mode of dealing with the world that emerges during the preschool period.

Language

Our understanding of the acquisition of language is evolving. Preschool children command significant computational skills and understanding of statistical patterns that allow them to learn about both language and causation. The 2 and 3 yr old child employs frequency distributions to identify phonetic units distinguishing words in his or her native language from other languages.

Language development occurs most rapidly between 2 and 5 yr of age. Vocabulary increases from 50-100 words to more than 2,000. Sentence structure advances from telegraphic phrases ("Baby cry") to sentences incorporating all of the major grammatical components. As a rule of thumb, between the ages of 2 and 5 yr, the number of words in a typical sentence equals the child's age (2 by age 2 yr, 3 by age 3 yr, and so on). By 21-24 mo, most children are using possessives ("My ball"), progressives (the "-ing" construction, as in "I playing"), questions, and negatives. By age 4 yr, most children can count to 4 and use the past tense; by age 5 yr, they can use the future tense. Children do not use figurative speech; they will only comprehend the literal meaning of words. Referring to an object as "light as a feather" may produce a quizzical look on a child.

It is important to distinguish between *speech* (the production of intelligible sounds) and *language,* which refers to the underlying mental act. Language includes both expressive and receptive functions. Receptive language (understanding) varies less in its rate of acquisition than does expressive language; therefore, it has greater prognostic importance (see Chapters 16 and 35).

Language acquisition depends critically on environmental input. Key determinants include the amount and variety of speech directed toward children and the frequency with which adults ask questions and encourage verbalization. Children raised in poverty typically perform lower on measures of language development compared to children from economically advantaged families.

Although experience influences the rate of language development, many linguists believe that the basic mechanism for language learning is "hard-wired" in the brain. Children do not simply imitate adult speech; they abstract the complex rules of grammar from the ambient language, generating implicit hypotheses. Evidence for the existence of such implicit rules comes from analysis of grammatical errors, such as the overgeneralized use of "-s" to signify the plural and "-ed" to signify the past ("We seed lots of mouses.").

Language is linked to both cognitive and emotional development. Language delays may be the first indication that a child has an intellectual disability, has an autism spectrum disorder, or has been maltreated. Language plays a critical part in the regulation of behavior through internalized "private speech" in which a child repeats adult prohibitions, first audibly and then mentally. Language also allows children to express feelings, such as anger or frustration, without acting them out; consequently, language-delayed children show higher rates of tantrums and other externalizing behaviors.

Preschool language development lays the foundation for later success in school. Approximately 35% of children in the United States may enter school lacking the language skills that are the prerequisites for acquiring literacy. Children from socially and economically disadvantaged backgrounds have an increased risk of school problems, making early detection, along with referral and enrichment, important. Although children typically learn to read and write in elementary school, critical foundations for literacy are established during the preschool years. Through repeated early exposure to written words, children learn about the uses of writing (telling stories or sending messages) and about its form (left to right, top to bottom). Early errors in writing, like errors in speaking, reveal that literacy acquisition is an active process involving the generation and revision of hypotheses. Programs such as Head Start are especially important for improving language skills for children from bilingual homes. Such parents should be reassured that although bilingual children do initially lag behind their monolingual peers in acquiring language, they learn the differing rules governing both languages. Bilingual children do not follow the same course of language development as monolingual children, but create a different system of language cues. Several cognitive advantages have been repeatedly demonstrated among bilingual compared to monolingual children.

Picture books have a special role not only in familiarizing young children with the printed word but also in the development of verbal language. Children's vocabulary and receptive language improve when their parents or caregivers consistently read to them. Reading aloud with a young child is an interactive process in which a parent repeatedly focuses the child's attention on a particular picture, asks questions, and then gives the child feedback (**dialogic reading**). The elements of shared attention, active participation, immediate feedback, repetition, and graduated difficulty make such routines ideal for language learning. Programs in which physicians provide books to preschool children have shown improvement in language skills among the children.

The period of rapid language acquisition is also when **developmental dysfluency** and **stuttering** are most likely to emerge; these can be traced to activation of the cortical motor, sensory, and cerebellar areas. Common difficulties include pauses and repetitions of initial sounds. Stress or excitement exacerbates these difficulties, which generally resolve on their own. Although 5% of preschool children will stutter, it will resolve in 80% of those children by age 8 yr. Children with stuttering should be referred for evaluation if it is severe, persistent, or associated with anxiety, or if parental concern is elicited. **Treatment** includes guidance to parents to reduce pressures associated with speaking.

Cognition

The preschool period corresponds to Piaget's preoperational (prelogical) stage, characterized by **magical thinking**, **egocentrism**, and **thinking that is dominated by perception**, not abstraction (see Table 6-2). Magical thinking includes confusing coincidence with causality, animism (attributing motivations to inanimate objects and events), and unrealistic beliefs about the power of wishes. A child might believe that people cause it to rain by carrying umbrellas, that the sun goes down because it is tired, or that feeling resentment toward a sibling can actually make that sibling sick. Egocentrism refers to a child's inability to take another's point of view and does not connote selfishness. A child might try to comfort an adult who is upset by bringing the adult a favorite stuffed animal. After 2 yr of age, the child develops a concept of herself or himself as an individual and senses the need to feel "whole."

Piaget demonstrated the dominance of perception over logic. In one experiment, water is poured back and forth between a tall, thin vase and a low, wide dish, and children are asked which container has more water. Invariably, they choose the one that looks larger (usually the tall vase), even when the examiner points out that no water has been added or taken away. Such misunderstandings reflect young children's developing hypotheses about the nature of the world as well as their difficulty in attending simultaneously to multiple aspects of a situation.

Recent work indicating that preschool children do have the ability to understand causal relationships has modified our understanding of the ability of preschool children to engage in abstract thinking. (see Chapter 7)

Imitation, central to the learning experience of preschool children, is now being recognized as a complex act because the of differences in the size of the operators (the adult and the child), different levels of dexterity, and even different outcomes. A child who watches an adult unsuccessfully attempt a simple act (unscrew a lid) will imitate the action—but often with the intended outcome, not the demonstrated but failed outcome. Thus "imitation" goes beyond the mere repetition of observed movements.

By age 3, children have self-identified their sex, and are actively seeking understanding of the meaning of gender identification. There is a developmental progression from rigidity (boys and girls have strict gender roles) in the early preschool years to a more flexible realistic understanding (boys and girls can have a variety of interests).

Play

Play involves learning, physical activity, socialization with peers, and practicing adult roles. Play increases in complexity and imagination, from simple imitation of common experiences, such as shopping and putting baby to bed (2 or 3 yr of age), to more extended scenarios involving singular events, such as going to the zoo or going on a trip (3 or 4 yr of age), to the creation of scenarios that have only been imagined, such as flying to the moon (4 or 5 yr of age). By age 3 yr, cooperative play is seen in activities such as building a tower of blocks together; later, more structured role-play activity, as in playing house, is seen. Play also becomes increasingly governed by rules, from early rules about asking (rather than taking) and sharing (2 or 3 yr of age), to rules that change from moment to moment, according to the desires of the players (4 and 5 yr of age), to the beginning of the recognition of rules as relatively immutable (5 yr of age). Electronic forms of play (games) are best if interactive and educational.

Play also allows for resolution of conflicts and anxiety and for creative outlets. Children can vent anger safely (spanking a doll), take on superpowers (dinosaur and superhero play), and obtain things that are denied in real life (a make-believe friend or stuffed animal). Creativity is particularly apparent in drawing, painting, and other artistic activities. Themes and emotions that emerge in a child's drawings often reflect the emotional issues of greatest importance for the child.

Difficulty distinguishing fantasy from reality colors a child's perception of what the child views in the media, through programming and advertising. One fourth of young children have a television set in their bedroom; a TV in the bedroom is associated with more hours of watching. The number of hours that preschoolers watch TV exceeds guidelines. Interactive quality educational programming in which children develop social relationships with the characters can increase learning. However, exposure to commercial television with violent content is associated with later behavior problems and because children younger than 8 yr are not able to comprehend the concept of persuasive intent, they are more vulnerable to television advertising.

Implications for Parents and Pediatricians

The significance of language as a target for assessment and intervention cannot be overestimated because of its central role as an indicator of cognitive and emotional development and a key factor in behavioral regulation and later school success. As language emerges, parents can support emotional development by using words that describe the child's feeling states ("You sound angry right now.") and urging the child to use words to express, rather than act out, feelings. Active imaginations will come into play when children offer explanations for misbehavior. A parent's best way of dealing with untruths is to address the event, not the child, and have the child participate in making things right.

Parents should have a regular time each day for reading or looking at books with their children. Programs such as Reach Out and Read, in which pediatricians give out picture books along with appropriate guidance during primary care visits, have been effective in increasing reading aloud and thereby promoting language development, particularly in lower-income families. Television and similar media should be limited to 2 hr/day of quality programming, and parents should be watching the programs with their children and debriefing their young children afterward. At-risk children, particularly those living in poverty, can better meet future school challenges if they have early high-quality experiences, such as Head Start.

Preoperational thinking constrains how children understand experiences of illness and treatment. Children begin to understand that bodies have "insides" and "outsides." Children should be given simple, concrete explanations for medical procedures and given some control over procedures if possible. Children should be reassured that they are not to blame when receiving a vaccine or venipuncture. An adhesive bandage will help to make the body whole again in a child's mind.

The active imagination that fuels play and the magical, animist thinking characteristic of preoperational cognition can also generate intense fears. More than 80% of parents report at least 1 fear in their preschool children. Refusal to take baths or to sit on the toilet may arise from the fear of being washed or flushed away, reflecting a child's immature appreciation of relative size. Attempts to demonstrate rationally that there are no monsters in the closet often fail, inasmuch as the fear arises from prerational thinking. However, this same thinking allows parents to be endowed with magical powers that can banish the monsters with "monster spray" or a night light. Parents should acknowledge the fears, offer reassurance and a sense of security, and give the child some sense of control over the situation. Use of the Draw-a-Person, in which a child is asked to draw the best person the child can, may help elucidate a child's viewpoint.

EMOTIONAL AND MORAL DEVELOPMENT

Emotional challenges facing preschool children include accepting limits while maintaining a sense of self-direction, reining in aggressive and sexual impulses, and interacting with a widening circle of adults and peers. At 2 yr of age, behavioral limits are predominantly external; by 5 yr of age, these controls need to be internalized if a child is to function in a typical classroom. Success in achieving this goal relies on prior emotional development, particularly the ability to use internalized images of trusted adults to provide a secure environment in times of stress. The love a child feels for important adults is the main incentive for the development of self-control.

Children learn what behaviors are acceptable and how much power they wield vis-à-vis important adults by testing limits. Testing increases when it elicits attention, even though that attention is often negative, and when limits are inconsistent. Testing often arouses parental anger or inappropriate solicitude as a child struggles to separate, and it gives rise to a corresponding parental challenge: letting go. Excessively tight

limits can undermine a child's sense of initiative, whereas overly loose limits can provoke anxiety in a child who feels that no one is in control.

Control is a central issue. Young children cannot control many aspects of their lives, including where they go, how long they stay, and what they take home from the store. They are also prone to lose internal control, that is, to have temper tantrums. Fear, overtiredness, inconsistent expectations, or physical discomfort can also evoke tantrums. Tantrums normally appear toward the end of the 1st yr of life and peak in prevalence between 2 and 4 yr of age. Tantrums lasting more than 15 min or regularly occurring more than 3 times/day may reflect underlying medical, emotional, or social problems.

Preschool children normally experience complicated feelings toward their parents that can include strong attachment and possessiveness toward the parent of the opposite sex, jealousy and resentment of the other parent, and fear that these negative feelings might lead to abandonment. These emotions, most of which are beyond a child's ability to comprehend or verbalize, often find expression in highly labile moods. The resolution of this crisis (a process extending over years) involves a child's unspoken decision to identify with the parents rather than compete with them. Play and language foster the development of emotional controls by allowing children to express emotions and role play.

Curiosity about genitals and adult sexual organs is normal, as is masturbation. Excessive masturbation interfering with normal activity, acting out sexual intercourse, extreme modesty, or mimicry of adult seductive behavior all suggests the possibility of sexual abuse or inappropriate exposure (see Chapter 40.1). Modesty appears gradually between 4 and 6 yr of age, with wide variations among cultures and families. Parents should begin to teach children about "private" body areas before school entry.

Moral thinking is constrained by a child's cognitive level and language abilities, but develops as the child continues her or his identity with the parents. Beginning before the 2nd birthday, the child's sense of right and wrong stems from the desire to earn approval from the parents and avoid negative consequences. The child's impulses are tempered by external forces; the child has not yet internalized societal rules or a sense of justice and fairness. Over time, as the child internalizes parental admonitions, words are substituted for aggressive behaviors. Finally, the child accepts personal responsibility. Actions will be viewed by damage caused, not by intent. Empathic responses to others' distress arise during the 2nd yr of life, but the ability to consider another child's point of view remains limited throughout this period. In keeping with a child's inability to focus on more than 1 aspect of a situation at a time, fairness is taken to mean equal treatment, regardless of circumstance. A 4 yr old will acknowledge the importance of taking turns, but will complain if he or she didn't get enough time. Rules tend to be absolute, with guilt assigned for bad outcomes, regardless of intentions.

Implications for Parents and Pediatricians

The importance of the preschooler's sense of control over his or her body and surroundings has implications for practice. Preparing the patient by letting the child know how the visit will proceed is reassuring. Tell the child what will happen, but don't ask permission unless you are willing to deal with a "no" answer. A brief introduction to "private parts" is warranted before the genital examination.

The visit of the 4 or 5 yr old should be entertaining, because of the child's ability to communicate, as well as the child's natural curiosity. Physicians should realize that all children are occasionally difficult. Guidance emphasizing appropriate expectations for behavioral and emotional development and acknowledging normal parental feelings of anger, guilt, and confusion should be part of all visits at this time. Parents should be queried about daily routines and their expectations of child behavior. Providing children with choices (all options being acceptable to the parent) and encouraging independence in self-care activities (feeding, dressing, and bathing) will reduce conflicts.

Although some cultures condone the use of corporal punishment for disciplining of young children, it is not an effective means of behavioral control. As children habituate to repeated spanking, parents have to spank ever harder to get the desired response, increasing the risk of serious injury. Sufficiently harsh punishment may inhibit undesired behaviors, but at great psychologic cost. Children mimic the corporal punishment that they receive; children who are spanked will have more aggressive behaviors later. Whereas spanking is the use of force, externally applied, to produce behavior change, **discipline** is the process that allows the child to internalize controls on behavior. Alternative discipline strategies should be offered, such as the "countdown," along with consistent limit setting, clear communication of rules, and frequent approval. Discipline should be immediate, specific to the behavior, and time-limited. Time-out for approximately 1 min/yr of age is very effective. A kitchen timer allows the parent to step back from the situation; the child is free when the timer rings.

Chapter 13

Middle Childhood

Susan Feigelman

Middle childhood (6-11 yr of age) is the period in which children increasingly separate from parents and seek acceptance from teachers, other adults, and peers. Children begin to feel under pressure to conform to the style and ideals of the peer group. Self-esteem becomes a central issue, as children develop the cognitive ability to consider their own self-evaluations and their perception of how others see them. For the first time, they are judged according to their ability to produce socially valued outputs, such as getting good grades, playing a musical instrument, or hitting home runs.

PHYSICAL DEVELOPMENT

Growth occurs **discontinuously,** in 3-6 irregularly timed spurts each year, but varies both within and among individuals. Growth during the period averages 3-3.5 kg (6.6-7.7 lb) and 6-7 cm (2.4-2.8 in) per year (Fig. 13-1). The head grows only 2 cm in circumference throughout the entire period, reflecting a slowing of brain growth. Myelinization continues into adolescence, with peak gray matter at 12-14 yr. Body habitus is more erect than previously, with long legs compared with the torso.

Growth of the midface and lower face occurs gradually. Loss of deciduous (baby) teeth is a more dramatic sign of maturation, beginning around 6 yr of age. Replacement with adult teeth occurs at a rate of about 4 per year, so that by age 9 yr, children will have 8 permanent incisors and 4 permanent molars. Premolars erupt by 11-12 yr of age (see Chapter 307). Lymphoid tissues hypertrophy, often giving rise to impressive tonsils and adenoids.

Muscular strength, coordination, and stamina increase progressively, as does the ability to perform complex movements, such as dancing or shooting baskets. Such higher-order motor skills are the result of both maturation and training; the degree of accomplishment reflects wide variability in innate skill, interest, and opportunity.

Physical fitness has declined among school-age children. Sedentary habits at this age are associated with increased lifetime risk of obesity, cardiovascular disease, academic achievement, and lower self-esteem (see Chapter 47). The number of overweight children and the degree of overweightness have been increasing, although recently at a slower rate (see Chapter 47). Only 15% of middle and junior high schools require physical education class at least 3 days/wk. One quarter of youth do not engage in any free-time physical activity, despite the recommendation for 1 hr of physical activity per day.

Perceptions of body image develop early during this period; children as young as 5 and 6 yr express dissatisfaction with their body image; by ages 8 and 9 yr many of these youth report trying to diet, often using

ill-advised regimens. Loss of control (binge) eating occurs among approximately 6% of children of this age.

Prior to puberty, the sensitivity of the hypothalamus and the pituitary changes, leading to increased gonadotropin synthesis. Interest in gender differences and sexual behavior increases progressively until puberty. Although this is a period when sexual drives are limited, masturbation is common, and children may be interested in differences between genders. Sexual maturity occurs earlier for both genders in the United States. Rates of maturation differ by geography, ethnicity, and country. These differences in maturation have implications for differing expectations of others about them based on sexual maturation.

Implications for Parents and Pediatricians

Middle childhood is generally a time of excellent health. However, children have variable sizes, shapes, and abilities. Children of this age compare themselves with others, eliciting feelings about their physical attributes and abilities. Fears of being "abnormal" can lead to avoidance of situations in which physical differences might be revealed, such as gym class or medical examinations. Children with actual physical disabilities may face special stresses. Medical, social, and psychologic risks tend to occur together.

Children should be asked about risk factors for obesity. Participation in physical activity, including organized sports or other organized activities can foster skill, teamwork, and fitness, as well as a sense of accomplishment, but pressure to compete when the activity is no longer enjoyable has negative effects. Counseling on establishing healthy eating habits and limited screen time should be given to all families. Prepubertal children should not engage in high-stress, high-impact sports, such as power lifting or tackle football, because skeletal immaturity increases the risk of injury (see Chapter 693).

COGNITIVE DEVELOPMENT

The thinking of early elementary school-age children differs qualitatively from that of preschool children. In place of magical, egocentric, and perception-bound cognition, school-age children increasingly apply rules based on observable phenomena, factor in multiple dimensions and points of view, and interpret their perceptions using physical laws. Piaget documented this shift from *preoperational* to *concrete logical operations.* When 5 yr olds watch a ball of clay being rolled into a snake, they might insist that the snake has "more" because it is longer. In contrast, 7 yr olds typically reply that the ball and the snake must weigh the same because nothing has been added or taken away or because the snake is both longer and thinner. This cognitive reorganization occurs at different rates in different contexts. In the context of social interactions with siblings, young children often demonstrate an ability to understand alternate points of view long before they demonstrate that ability in their thinking about the physical world. Understanding time and space constructs occurs in the later part of this period.

The concept of "**school readiness**" has evolved. The American Academy of Pediatrics recommends following an "interactional relational" model in which the focus is on the child, the environment and the interactions therein. This model aid explicitly asserts that all children can learn and that the educational process is reciprocal between the child and the school. The model is developmentally based as it recognizes the importance of early experiences for later development. Rather than delaying school entry, high quality early education programs may be the key to ultimate school success.

School makes increasing cognitive demands on the child. Mastery of the elementary curriculum requires that a large number of perceptual, cognitive, and language processes work efficiently (Table 13-1), and children are expected to attend to many inputs at once. The 1st 2-3 yr of elementary school are devoted to acquiring the fundamentals: reading, writing, and basic mathematics skills. By 3rd grade, children need to be able to sustain attention through a 45 min period and the curriculum requires more complex tasks. The goal of reading a paragraph is no longer to decode the words, but to understand the content; the goal of writing is no longer spelling or penmanship, but composition. The volume of work increases along with the complexity.

Cognitive abilities interact with a wide array of attitudinal and emotional factors in determining classroom performance. These factors include external rewards (eagerness to please adults and approval from peers) and internal rewards (competitiveness, willingness to work for a delayed reward, belief in one's abilities, and ability to risk trying when

Table 13-1 Selected Perceptual, Cognitive, and Language Processes Required for Elementary School Success

PROCESS	DESCRIPTION	ASSOCIATED PROBLEMS
PERCEPTUAL		
Visual analysis	Ability to break a complex figure into components and understand their spatial relationships	Persistent letter confusion (e.g., between *b, d,* and *g*); difficulty with basic reading and writing and limited "sight" vocabulary
Proprioception and motor control	Ability to obtain information about body position by feel and unconsciously program complex movements	Poor handwriting, requiring inordinate effort, often with overly tight pencil grasp; special difficulty with timed tasks
Phonologic processing	Ability to perceive differences between similar sounding words and to break down words into constituent sounds	Delayed receptive language skill; attention and behavior problems secondary to not understanding directions; delayed acquisition of letter-sound correlations (phonetics)
COGNITIVE		
Long-term memory, both storage and recall	Ability to acquire skills that are "automatic" (i.e., accessible without conscious thought)	Delayed mastery of the alphabet (reading and writing letters); slow handwriting; inability to progress beyond basic mathematics
Selective attention	Ability to attend to important stimuli and ignore distractions	Difficulty following multistep instructions, completing assignments, and behaving well; problems with peer interaction
Sequencing	Ability to remember things in order; facility with time concepts	Difficulty organizing assignments, planning, spelling, and telling time
LANGUAGE		
Receptive language	Ability to comprehend complex constructions, function words (e.g., if, when, only, except), nuances of speech, and extended blocks of language (e.g., paragraphs)	Difficulty following directions; wandering attention during lessons and stories; problems with reading comprehension; problems with peer relationships
Expressive language	Ability to recall required words effortlessly (word finding), control meanings by varying position and word endings, and construct meaningful paragraphs and stories	Difficulty expressing feelings and using words for self-defense, with resulting frustration and physical acting out; struggling during "circle time" and in language-based subjects (e.g., English)

success is not ensured). Success predisposes to success, whereas failure impacts self-esteem and reduces self-efficacy, diminishing a child's ability to take future risks.

Children's intellectual activity extends beyond the classroom. Beginning in the 3rd or 4th grade, children increasingly enjoy strategy games and wordplay (puns and insults) that exercise their growing cognitive and linguistic mastery. Many become experts on subjects of their own choosing, such as sports trivia, or develop hobbies, such as special card collections. Others become avid readers or take on artistic pursuits. Whereas board and card games were once the usual leisure time activity of youth, video, computer and other electronic games currently fill this need.

Implications for Parents and Pediatricians

Pediatricians have an important role in preparing their patients for school entrance by promoting health through immunizations, adequate nutrition, appropriate recreation and screening for physical, developmental, and cognitive disorders. The American Academy of Pediatrics recommends that pediatric providers promote the "5 Rs" of early education: (1) reading as a daily family activity; (2) rhyming, playing, and cuddling together; (3) routines and regular times for meals, play, and sleep; (4) reward through praise for successes; and (5) reciprocal nurturing relationships,

Concrete operations allow children to understand simple explanations for illnesses and necessary treatments, although they may revert to prelogical thinking when under stress. A child with pneumonia may be able to explain about white cells fighting the "germs" in the lungs, but still secretly harbors the belief that the sickness is a punishment for disobedience.

As children are faced with more abstract concepts, academic and classroom behavior problems emerge and come to the pediatrician's attention. Referrals may be made to the school for remediation or to community resources (medical or psychologic) when appropriate. The causes may be one or more of the following: deficits in perception (vision and hearing); specific learning disabilities; global cognitive delay (mental retardation); primary attention deficit; and attention deficits secondary to family dysfunction, depression, anxiety, or chronic illness (see Chapters 16 and 32). Children whose learning style does not fit the classroom culture may have academic difficulties and need assessment before failure sets in. Simply having a child repeat a failed grade rarely has any beneficial effect and often seriously undercuts the child's self-esteem. In addition to finding the problem areas, identifying each child's strengths is important. Educational approaches that value a wide range of talents ("multiple intelligences") beyond the traditional ones of reading, writing, and mathematics may allow more children to succeed.

The change in cognition allows the child to understand "if/when" clauses. Increased responsibilities and expectations accompany increased rights and privileges. Discipline strategies should move toward negotiation and a clear understanding of consequences, including removal of privileges for infringements.

SOCIAL, EMOTIONAL, AND MORAL DEVELOPMENT

Social and Emotional Development

In this period, energy is directed toward creativity and productivity. Changes occur in 3 spheres: the home, the school, and the neighborhood. Of these, the home and family remain the most influential. Increasing independence is marked by the first sleepover at a friend's house and the first time at overnight camp. Parents should make demands for effort in school and extracurricular activities, celebrate successes, and offer unconditional acceptance when failures occur. Regular chores, associated with an allowance, provide an opportunity for children to contribute to family functioning and learn the value of money. These responsibilities may be a testing ground for psychologic separation, leading to conflict. Siblings have critical roles as competitors, loyal supporters, and role models.

The beginning of school coincides with a child's further separation from the family and the increasing importance of teacher and peer relationships. Social groups tend to be same-sex, with frequent changing of membership, contributing to a child's growing social development and competence. Popularity, a central ingredient of self-esteem, may be won through possessions (having the latest electronic gadgets or the right clothes), as well as through personal attractiveness, accomplishments, and actual social skills. Children are aware of racial differences and are beginning to form opinions about racial groups that impact their relationships.

Some children conform readily to the peer norms and enjoy easy social success. Those who adopt individualistic styles or have visible differences may be teased. Such children may be painfully aware that they are different, or they may be puzzled by their lack of popularity. Children with deficits in social skills may go to extreme lengths to win acceptance, only to meet with repeated failure. Attributions conferred by peers, such as funny, stupid, bad, or fat, may become incorporated into a child's self-image and affect the child's personality, as well as school performance. Parents may have their greatest effect indirectly, through actions that change the peer group (moving to a new community or insisting on involvement in structured after-school activities).

In the neighborhood, real dangers, such as busy streets, bullies, and strangers, tax school-age children's common sense and resourcefulness. Interactions with peers without close adult supervision call on increasing conflict resolution or pugilistic skills. Media exposure to adult materialism, sexuality, substance use and violence may be frightening, reinforcing children's feeling of powerlessness in the larger world. Compensatory fantasies of being powerful may fuel the fascination with heroes and superheroes. A balance between fantasy and an appropriate ability to negotiate real-world challenges indicates healthy emotional development.

Moral Development

Although by age 6 yr most children will have a conscience (internalized rules of society), they vary greatly in their level of moral development. For the younger youth, many still subscribe to the notion that, rules are established and enforced by an authority figure (parent or teacher) and decision-making is guided by self-interest (avoidance of negative and receipt of positive consequences). The needs of others are not strongly considered in decision-making. As they grow older, most will recognize not only their own needs and desires, but also those of others, although personal consequences are still the primary driver of behavior. Social behaviors that are socially undesirable are considered to be wrong. By age 10-11 yr the combination of peer pressure, a desire to please authority figures as well as an understanding of reciprocity (treat others as you wish to be treated) shapes the child's behavior.

Implications for Parents and Pediatricians

Children need unconditional support as well as realistic demands as they venture into a world that is often frightening. A daily query from parents over the dinner table or at bedtime about the good and bad things that happened during the child's day may uncover problems early. Parents may have difficulty allowing the child independence or may exert excessive pressure on their children to achieve academic or competitive success. Children who struggle to meet such expectations may have behavior problems or psychosomatic complaints.

Many children face stressors that exceed the normal challenges of separation and success in school and the neighborhood. Divorce affects nearly 50% of children. Domestic violence, parental substance abuse, and other mental health problems may also impair a child's ability to use home as a secure base for refueling emotional energies. In many neighborhoods, random violence makes the normal development of independence extremely dangerous. Older children may join gangs as a means of self-protection and a way to attain recognition and belong to a cohesive group. Children who bully others, and/or are victims of bullying, should be evaluated, since this behavior is associated with mood disorders, family problems, and school adjustment problems. Parents should reduce exposure to hazards where possible. Because of the risk of unintentional firearm injuries to children, parents should be encouraged to ask parents of playmates whether a gun is kept in

their home and, if so, how it is secured. The high prevalence of adjustment disorders among school-age children attests to the effects of such overwhelming stressors on development.

Pediatrician visits are infrequent in this period; therefore each visit is an opportunity to assess children's functioning in all contexts (home, school, neighborhood). Maladaptive behaviors, both internalizing and externalizing, occur when stress in any of these environments overwhelms the child's coping responses. Due to continuous exposure and the strong influence of media (programming and advertisements) on children's beliefs and attitudes, parents must be alert to exposures from the television and Internet. An average American youth spends over 6 hr/day with a variety of media, and ⅔ of these children have a television in their bedrooms. Parents should be advised to remove the television from their children's rooms, limit viewing to 2 hr/day, and monitor what programs children watch. The Draw-a-Person (for ages 3-10 yr, with instructions to "draw a complete person") and Kinetic Family Drawing (beginning at age 5 yr, with instructions to "draw a picture of everyone in your family doing something") are useful office tools to assess a child's functioning.

Chapter 15

Assessment of Growth

Virginia A. Keane

Many biophysiologic and psychosocial problems can adversely affect growth, and aberrant growth may be the first sign of an underlying problem. The most powerful tool in growth assessment is the growth chart (see Figs. 11-1, 11-2, 13-1, and 15-1) used in combination with accurate measurements of height, weight, head circumference, and calculation of the body mass index (BMI).

PROCEDURES FOR ACCURATE MEASUREMENT

Growth assessment requires accurate measurement. Weight, in pounds or kilograms, must be determined using an accurate scale. For infants and toddlers, weight, length, and head circumference are obtained. These measures should be performed with the infant naked, and ideally, repeated measures should be performed on the same equipment. Head circumference is determined using a flexible tape measure run from the supraorbital ridge to the occiput in the path that leads to the largest possible measurement. Length is most accurately measured by 2 examiners (1 to position the child), with the child supine on a measuring board. For older children, the measure is stature or height, taken without shoes, using a stadiometer. Measurements obtained in alternative manners, such as marking examination paper at the foot and head of a supine infant, or using a simple wall growth chart with a book or ruler on the head can lead to inaccuracy that may render the measurement useless. It is essential to compare measurements with previous growth trends, repeat any that are inconsistent, and plot results longitudinally.

DERIVATION AND INTERPRETATION OF GROWTH CHARTS

In 2000, the Centers for Disease Control and Prevention (CDC) published new growth charts, replacing the 1977 version. Modifications since then have not changed the data points. Set 1 includes the 5th to 95th percentiles; set 2, the 3rd to 97th percentiles. These charts contain data from national surveys conducted by the National Center for Health Statistics between 1963 and 1994. Data are representative of the U.S. population, both demographically and in terms of breastfeeding prevalence. Methodologic steps have assured that the increase in the prevalence of obesity has not unduly raised the upper limits of normal. Several deficiencies of the older charts have been corrected, such as the overrepresentation of bottlefed infants and the reliance on a local data set for the infant charts. The disjunction between length and height, when moving from the infant curves to those for older children, no longer exists. The charts include curves for plotting BMI for ages 2-20 yr rather than weight for height, facilitating identification of obesity.

The data are presented in 5 standard gender-specific charts: (1) weight for age; (2) height (length and stature) for age; (3) head circumference for age; (4) weight for height (length and stature) for infants; and (5) BMI for age for children over 2 yr of age (see Fig. 15-1; also see Figs. 11-1, 11-2, and 13-1). The charts are available at http://www.cdc.gov/growthcharts/.

Each chart is composed of percentile curves, representing the cross-sectional distribution of weight, length, stature, head circumference, weight for length, or BMI at each age. The percentile curve indicates the percentage of children at a given age on the *x*-axis whose measured value falls below the corresponding value on the *y*-axis. On the weight chart for boys 0-36 mo of age (see Fig. 11-2*A*), the 9 mo age line intersects the 25th percentile curve at 8.6 kg, indicating that 25% of the 9 mo old boys in the National Center for Health Statistics sample weigh less than 8.6 kg (75% weigh more). Similarly, a 9 mo old boy weighing more than 11.2 kg is heavier than 95% of his peers. The median or 50th percentile is also termed the *standard value,* in the sense that the standard height for a 7 mo old girl is 67 cm (see Fig. 11-2*B*). The weight-for-height charts (see Fig. 11-1) are constructed in an analogous fashion, with length or stature in place of age on the *x*-axis; the median or standard weight for a girl measuring 110 cm is 18.6 kg.

For infants, the revised CDC charts represent observed but not necessarily optimal growth because they still incorporate data from many bottlefed infants. Rates of initiation of breastfeeding in the United States have more than doubled from 26% in 1970 to 74% in 2005, but nationally only 49% continue to breastfeed at 6 mo, and only 27% continue until 12 mo. Compared with current standards, an exclusively breastfed infant would be expected to plot higher for weight in the 1st 6 mo, but relatively lower in the second half of the 1st yr. Awareness of this growth difference should prevent overidentification of growth problems in breastfed infants.

In an effort to set an internationally usable standard for optimal growth in children, the World Health Organization (WHO) released growth charts based on the Multicenter Growth Reference Study for young children in 2006 and for children 5-19 in 2007. Rather than describing the growth of typical children, the Multicenter Growth Reference Study describes the growth of children who are predominantly breastfed and raised under optimal conditions. Six study sites representing 5 continents were included: United States, Brazil, Norway, Ghana, Oman, and India. Use of the WHO charts in developing nations results in identification of many more children as malnourished and eligible for therapeutic feeding programs. Their use in the United States generally results in many fewer infants being identified as underweight (comparison of curves shown in Fig. 15-2), although studies have found overidentification of poor growth even using these curves. The CDC recommends the use of WHO charts for U.S. children from birth to 24 mo. Adoption of these charts in the United States has been slow. Charts are available online at http://www.who.int/childgrowth/standards/en/.

For adolescents, caution must be used in applying cross-sectional charts. Growth during adolescence is linked temporally to the onset of puberty, which varies widely. By using cross-sectional data based on chronological age, the charts combine youth who are at different stages of maturation. Normal variations in the timing of the growth spurt can lead to misdiagnosis of growth abnormalities. The data for 12 yr old boys include both early-maturing boys who are at the peak of their growth spurts and late-maturing ones who are still growing at their prepubertal rate. The net result is to artificially level off the growth peak, making it appear that adolescents grow more gradually and for a longer period than they do. When additional precision is necessary, growth charts derived from longitudinal data, such as the height velocity charts of Tanner and colleagues, are recommended.

Specialized charts have been developed for U.S. children with various conditions, including very-low birthweight and prematurity; Down, Turner, and Klinefelter syndromes; cerebral palsy; and achondroplasia. In addition, growth charts for children of distinct ethnic groups or nationalities may be found on the World Wide Web.

BMI for age complements the standard growth charts for children older than 2 yr of age. BMI can be calculated as weight in kilograms/(height in meters)^2 or weight in pounds/(height in inches)$^2 \times 703$, with fractions of pounds and inches expressed as decimals. Values may be plotted on standard BMI charts (see Fig. 15-1). These calculations can be easily performed electronically using a variety of desktop and handheld devices. BMI percentile varies with age over childhood: a 6 yr old girl with a BMI of 21 is overweight, whereas a 16 yr old girl with the same BMI is just above the 50th percentile.

Electronic medical records (EMRs) include growth charts and usually calculate and plot BMIs. However, the origin of the growth charts that are included in the EMRs used by a pediatrician may be unknown to the pediatrician; consequently, pediatricians are cautioned to contact their EMR company and assure that the CDC and WHO growth charts are available in the EMRs to assure accurate assessment.

Height velocity charts, which evaluate the rate of growth per year, are considered by many to give a more sensitive and specific indicator of abnormal growth. They are used primarily by pediatric endocrinologists. Although many parents think it is important to see growth charts, parents may misinterpret their meaning. Clinicians are cautioned to provide clear interpretation when using growth charts as visual aids.

ANALYSIS OF GROWTH PATTERNS

Growth is a process rather than a static quality. An infant at the 5th percentile of weight for age may be growing normally, may be failing to grow, or may be recovering from growth failure, depending on the trajectory of the growth curve. Infants may lose up to 10% of their birth weight in the 1st wk of life and regain it by the end of the 2nd wk. They will then gain steadily at a rate of 20-30 g/day for the 1st 3 mo. Table 15-1 gives typical growth and calorie requirements for children through age 6 yr. Formulas are available for the estimation of average height

and weight and height for children of various ages, but given their complexity and the easy availability of growth charts, use of the latter is preferable.

Despite the facts that the National Center for Health Statistics charts represent cross-sectional rather than longitudinal data and that children tend to grow in spurts, most children tend to track along a percentile, referred to as *following the curve*. A normal exception commonly occurs between 6 and 18 mo of life. For full-term infants, size at birth reflects the influence of the uterine environment; however, size at 2 yr correlates with mean parental height, reflecting the influence of genes. Between 6 and 18 mo of age, infants may shift percentiles upward or downward toward their genetic potential. Thereafter, most children will track along a growth percentile, with variation within 2 large percentile bands (a small infant might track between the 5th and 25th percentiles, a large one between the 75th and 95th). This tracking often represents the midparental height and a corresponding weight, where **midparental height** is calculated in inches as follows:

- Boys: [(maternal height + 5) + paternal height]/2
- Girls: [maternal height + (paternal height − 5)]/2
- 13 cm (instead of ± 5 in) if using metric units

It is important to correct for various factors in plotting and interpreting growth charts. For **premature infants**, overdiagnosis of growth failure can be avoided by using growth charts developed specifically for this population. A cruder method, subtracting the weeks of prematurity from the postnatal age when plotting growth parameters, does not capture the variability in growth velocity that very-low birthweight infants demonstrate. Although very-low birthweight infants may continue to show catchup growth through early school age, most achieve weight catchup during the 2nd yr and height catchup by 2.5 yr, barring medical complications (see Chapter 97). For children with particularly tall or short parents, there is a risk of overdiagnosing growth disorders if parental height is not taken into account or, conversely, of underdiagnosing growth disorders if parental height is accepted uncritically as the explanation.

The analysis of growth patterns and the detection of aberrant growth patterns provide critical information for the detection of pathologic conditions. Calculation of daily and monthly growth, such as weight gain in g/day (see Table 15-1), allows more precise comparison of growth rate to the norm. Weight loss, or failure to gain normally, is often the first sign of pathology.

The diagnosis of **failure to thrive** (see Chapter 41), usually a diagnosis of children younger than 3 yr of age, is considered if a child's weight is below the 5th percentile, if it drops down more than 2 major percentile lines, or if weight for height is less than the 5th percentile. Weight for height below the 5th percentile remains the single best growth chart indicator of acute undernutrition. A BMI less than the 5th percentile also indicates that a child is underweight. Brief periods of weight loss or poor weight gain are usually rapidly corrected and do not permanently affect size. Children who have been chronically malnourished may be short (stunted) as well as thin, so that their weight-for-height curves may appear relatively normal. Chronic, severe undernutrition in infancy may depress head growth, which may be an ominous predictor of later cognitive disability. Low weight for age or height or weight loss may be referred to as wasting. When growth parameters fall below the 5th percentile, values can be expressed as percentages of the median, or standard, value. A 12 mo old girl weighing 7.1 kg is at 75% of the median weight (9.5 kg) for her age.

Another way to evaluate weight is to determine the ideal body weight for height and compare the current weight to the ideal body weight for length or height. A 15 mo old boy who is 79 cm is at the 50th percentile. The ideal weight is 12 kg. If he weighs 8 kg (<5th percentile), he is 67% of ideal body weight, an indication of severe wasting. Table 15-2 provides interpretation of percent ideal body weight from obese to severe wasting.

Extremes of height or weight can also be expressed in terms of the age for which they would represent the standard or median. For instance, a 30 mo old girl who is 79 cm (<5%) is at the 50th percentile for a 16 mo old. Thus the height age is 16 mo. Weight age can also be expressed this way.

Table 15-2	Interpretation of Percent of Ideal Body Weight
>120%	Obese
110-120%	Overweight
90-110%	Normal variation
80-90%	Mild wasting
70-80%	Moderate wasting
<70%	Severe wasting

Linear growth deficiency (stunting) is more likely to be a result of congenital, constitutional, familial, or endocrine causes than caused by nutritional deficiency (see Chapter 46). In endocrine disorders, length or height declines first or at the same time as weight; weight for height is normal or elevated. In nutritional insufficiency, weight declines before length, and weight for height is low (unless there has been chronic stunting). Figure 15-3 depicts typical growth curves for 4 classes of decreased linear growth. In congenital pathologic short stature, an infant is born small and growth gradually tapers off throughout infancy. Causes include chromosomal abnormalities (Turner syndrome, trisomy 21; see Chapter 81), perinatal infection, extreme prematurity, and teratogens (phenytoin, alcohol) (see Chapter 96). In constitutional growth delay, weight and height decrease near the end of infancy, parallel the norm through middle childhood, and accelerate toward the end of adolescence. Adult size is normal. In familial short stature, both the infant and the parents are small; growth runs parallel to and just below the normal curves.

Obesity affects large numbers of children. Growth charts can confirm an impression of obesity if the weight for height exceeds 120% of the standard (median) weight for height. According to the CDC, a BMI over the 95th percentile indicates obesity and a BMI between the 85th and 95th percentiles indicates overweight. Although widely accepted as the best clinical measure of under- and overweight, BMI may not provide an accurate index of adiposity, because it does not differentiate lean tissue and bone from fat. Measurement of the triceps, subscapular, and suprailiac skinfold thickness can be used to estimate adiposity; considerable experience is needed for accuracy. The *American Academy of Pediatrics Nutrition Handbook,* 6th edition, questions the use of fat folds to estimate total body fat, noting that the method has not been validated in young children and that basic assumptions of the method, that subcutaneous fat is a marker of total fat and that measured sites represent average skin fat thickness, are not true. Other methods of measuring fat, such as hydrodensitometry, bioelectrical impedance, and total body water measurement are used in research, but not in clinical evaluation.

OTHER INDICES OF GROWTH

Body Proportions

Body proportions follow a predictable sequence of changes with development. The head and trunk are relatively large at birth, with progressive lengthening of the limbs throughout development, particularly during puberty. The **lower-body segment** is defined as the length from the symphysis pubis to the floor, and the **upper-body segment** is the height minus the lower-body segment. The ratio of upper-body segment divided by lower-body segment (U/L ratio) equals approximately 1.7 at birth, 1.3 at 3 yr of age, and 1.0 after 7 yr of age. Higher U/L ratios are characteristic of short-limb dwarfism or bone disorders, such as rickets.

Skeletal Maturation

Reference standards for bone maturation facilitate estimation of bone age (see Table 10-3). Bone age correlates well with stage of pubertal development and can be helpful in predicting adult height in early- or late-maturing adolescents. In familial short stature, the bone age is normal (comparable to chronological age). In constitutional delay,

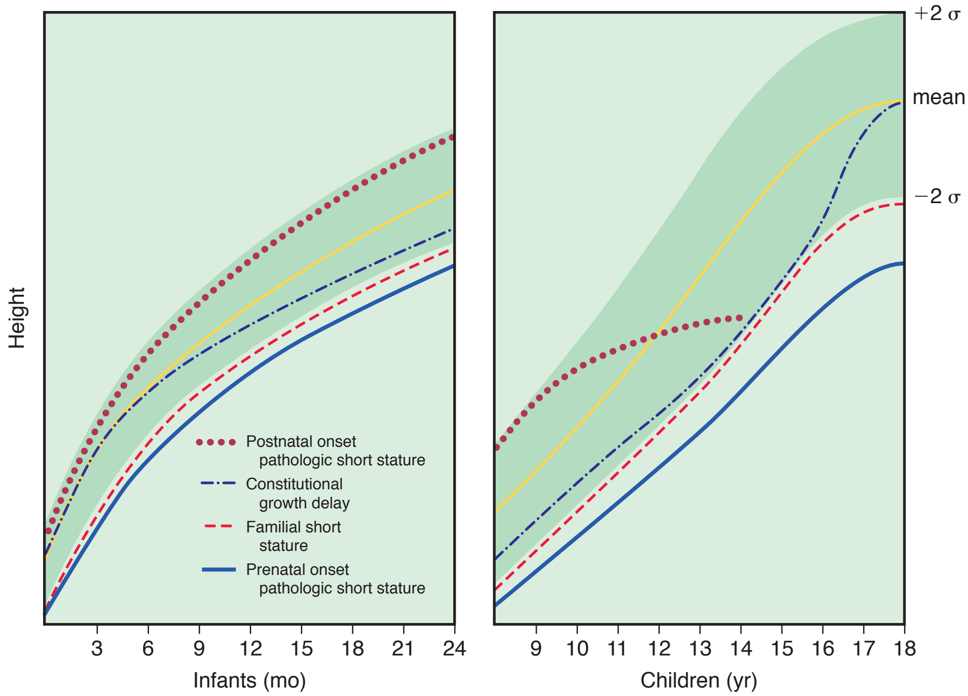

Figure 15-3 Height-for-age curves of the 4 general causes of proportional short stature: postnatal onset pathologic short stature, constitutional growth delay, familial short stature, and prenatal onset short stature. *(From Mahoney CP: Evaluating the child with short stature, Pediatr Clin North Am 34:825, 1987.)*

Table 15-3 Chronology of Human Dentition of Primary or Deciduous and Secondary or Permanent Teeth

	Calcification		Age at Eruption		Age at Shedding	
	BEGINS AT	COMPLETE AT	MAXILLARY	MANDIBULAR	MAXILLARY	MANDIBULAR
PRIMARY TEETH						
Central incisors	5th fetal mo	18-24 mo	6-8 mo	5-7 mo	7-8 yr	6-7 yr
Lateral incisors	5th fetal mo	18-24 mo	8-11 mo	7-10 mo	8-9 yr	7-8 yr
Cuspids (canines)	6th fetal mo	30-36 mo	16-20 mo	16-20 mo	11-12 yr	9-11 yr
First molars	5th fetal mo	24-30 mo	10-16 mo	10-16 mo	10-12 yr	10-12 yr
Second molars	6th fetal mo	36 mo	20-30 mo	20-30 mo	10-12 yr	11-13 yr
SECONDARY TEETH						
Central incisors	3-4 mo	9-10 yr	7-8 yr	6-7 yr		
Lateral incisors	Max, 10-12 mo Mand, 3-4 mo	10-11 yr	8-9 yr	7-8 yr		
Cuspids (canines)	4-5 mo	12-15 yr	11-12 yr	9-11 yr		
First premolars (bicuspids)	18-21 mo	12-13 yr	10-11 yr	10-12 yr		
Second premolars (bicuspids)	24-30 mo	12-14 yr	10-12 yr	11-13 yr		
First molars	Birth	9-10 yr	6-7 yr	6-7 yr		
Second molars	30-36 mo	14-16 yr	12-13 yr	12-13 yr		
Third molars	Max, 7-9 yr Mand, 8-10 yr	18-25 yr	17-22 yr	17-22 yr		

Mand, Mandibular; Max, maxillary.
Adapted from a chart prepared by P.K. Losch, Harvard School of Dental Medicine, who provided the data for this table.

endocrinologic short stature, and undernutrition, the bone age is low and comparable to the height age. Skeletal maturation is linked more closely to sexual maturity rating than to chronological age. It is more rapid and less variable in girls than in boys.

Dental Development

Dental development includes mineralization, eruption, and exfoliation (Table 15-3). Initial mineralization begins as early as the 2nd trimester (mean age for central incisors, 14 wk) and continues through 3 yr of age for the primary (deciduous) teeth and 25 yr of age for the permanent teeth. Mineralization begins at the crown and progresses toward the root. Eruption begins with the central incisors and progresses laterally. Exfoliation begins at about 6 yr of age and continues through 12 yr of age. Eruption of the permanent teeth may follow exfoliation immediately or may lag by 4-5 mo. The timing of dental development is poorly correlated with other processes of growth and maturation. **Delayed eruption** is usually considered when there are no teeth by approximately 13 mo of age (mean + 3 SD). Common causes include hypothyroid, hypoparathyroid, familial, and (the most common) idiopathic. Individual teeth may fail to erupt because of mechanical blockage (crowding, gum fibrosis). Causes of **early exfoliation** include histiocytosis X, cyclic neutropenia, leukemia, trauma, and idiopathic factors. Nutritional and metabolic disturbances, prolonged illness, and certain medications (tetracycline) commonly result in discoloration or malformations of the dental enamel. A discrete line of pitting on the enamel suggests a time-limited insult.

Chapter 16

Developmental-Behavioral Screening and Surveillance

Frances Page Glascoe, Kevin P. Marks, and Nerissa S. Bauer

The term *developmental–behavioral* refers to children's language, motor, cognitive/academic, self-help, and social–emotional status (a term that also embraces conduct, mental health, attention, and well-being). At well-child visits, development and behavior are the most common topic in parent–professional discussions. Early developmental–behavior problems are common (20-25%) but not benign. Left untreated, early deficits often burgeon into school failure and secondary mental health problems. The consequences include leaving high school before graduating (with rates in inner cities and among minority youth ranging as high as 50%), unemployment, incarceration, and teen pregnancy.

To prevent and address problems, clinicians must screen for existing limitations and risks.

MEASURABLE DELAYS

Among the many types of developmental–behavioral conditions, language problems are the most common (17.5% at 30-36 mo) (see Chapter 35). Delays in language development are often overlooked by healthcare providers, particularly when accurate screening/surveillance tools are not used. Other common conditions are social–emotional/behavioral/mental health disorders (9.5-14.2%), attention-deficit/hyperactivity disorder (7.8%) (see Chapter 33), learning disabilities (6.5%), intellectual disabilities (1.2%) (see Chapter 36), and autism spectrum disorders (0.6-1.1%) (see Chapter 30). Less common conditions include cerebral palsy and other orthopedic/motor impairments (0.23%) (see Chapter 598.1), hearing impairment (0.12%) (see Chapters 636-643), vision impairment (0.8%) (see Chapters 618-635), and conditions associated with disabilities (e.g., Down syndrome and fragile X syndrome [see Chapter 81], traumatic brain injury [see Chapter 68]).

PSYCHOSOCIAL RISK

Many children at risk for school failure lack measurable deficits in early childhood but have markers in the form of multiple risk factors that are strong predictors of future problems. Psychosocial risks include parents with less than a high school education; parental mental health problems such as depression or anxiety; housing or food instability; ethnic or linguistic minority; single parent; 3 or more children in the home; and parenting styles that are neglectful or authoritarian (e.g., highly directive, punitive, limited verbal communication such as talking about children's interests or book-sharing). Such risks eventually lead to developmental–behavioral delays, and result in children entering kindergarten behind their peers, being held back in grade, dropping out of high school, etc. Although psychosocial risk factors are common in children with a history of abuse or neglect, children in many other families are also at-risk.

EARLY INTERVENTION SERVICES AND ELIGIBILITY CRITERIA

If intervention is instituted prior to school entrance, many problems can be prevented and all can be ameliorated. Early intervention takes many forms, requiring varying degrees of intensity.

Developmental–behavioral promotion in primary care is one form of intervention and recommended at all visits. Clinicians identify and intervene with difficulties (e.g., with parent–child interactions and children's behavior), address parents' concerns and provide guidance on child-rearing and other issues. Role-playing, coaching, and verbal advice coupled with take-home information handouts are optimal approaches, although follow-up is needed to determine whether parents capitalized on directives or whether more intensive parent education is needed (e.g., parenting classes). Early intervention in primary care also involves identifying delays, risk factors for future delays, and referring for services more intensive than brief in-office counseling;

For children with psychosocial risk factors but without measurable delays, referrals are needed to a range of services such as Head Start/Early Head Start or quality daycare programs. Families often benefit from parent training classes or mental health interventions and referrals to social work services (e.g., for housing and food assistance, help with domestic violence). Older children with risk factors, benefit from dropout prevention assistance, including after-school tutoring, Boys and Girls Club, summer school, and mentoring programs.

For children with measurable delays (and those at extreme risk such as children in foster care) **referrals are needed to services funded by the Individuals with Disabilities Education Act** (IDEA). Very young children with delays, (i.e., birth to 3 yr of age) are eligible under the broad category of "developmental delay," defined as a single 40% departure or two 25% departures from typical performance in various developmental domains (e.g., receptive language, expressive language, fine motor, gross motor, social–emotional, cognitive/preacademic, and behavior). Because screening measures identify probable strengths and weaknesses but not the extent of deficits, clinicians should refer to IDEA programs for free evaluations to determine eligibility. When children are 3 yr of age, IDEA programs (administered by the public schools) provide detailed evaluations leading to definitive diagnoses and to a range of special education services and adjunctive therapies.

PRIMARY CARE CHALLENGES IN EARLY DETECTION

Despite the serious long-term consequences of psychosocial risk factors, delays and disabilities, only approximately 30% of children with developmental–behavioral problems are detected by primary care providers prior to school entrance, which means that most children with problems miss opportunities for early intervention. There are several reasons for underdetection in primary care:

- **Overconfidence in the effectiveness of informal identification methods** (e.g., ad-hoc questions to parents and milestones checklists such as those embedded in age-specific encounter forms, even if items are drawn from lengthier standardized measures such as the Denver Developmental Screening Test). Informal approaches are of little benefit to patients (or clinicians) because they lack validity, proof of accuracy, and definitive criteria for making referral decisions;
- **Overdependence on clinical judgment and failure to scrutinize the seemingly asymptomatic**. Dysmorphology and organicity are not present in the majority of children with disabilities;
- **Overfocusing on symptoms and thus missing underlying issues**. For example, behavior problems are often the presenting complaint, but many children with developmental deficits act out in frustration due to difficulties understanding what is being asked or expressing thoughts, desires, and feelings in words;
- **Lack of familiarity with and deployment of accurate screening tools effective for busy primary care settings**;
- **An erroneous sense that quality measures take more time than informal approaches**;
- **Excessive optimism about the effectiveness of brief in-office advice when children have measured delays**, and thus deferring rather than referring. Children rarely outgrow developmental–behavioral problems in the absence of intervention;
- **Discomfort at delivering difficult news**. Clinicians require skill at conducting interviews in which difficult news is delivered in a manner that is supportive, positive, and impels families to follow through with recommendations.

POLICIES OF THE AMERICAN ACADEMY OF PEDIATRICS

The American Academy of Pediatrics (AAP) recommends a combination of screening and surveillance at all well-visits.

Screening refers to the administration of brief, standardized, and validated instruments shown to have high sensitivity in detecting children with probable problems and high specificity in determining when children probably do not have problems. Screening for delays should occur across all domains: language (expressive and receptive), motor (gross and fine), cognitive/academic (including features of autism spectrum disorder), self-help, and social–emotional skills (including conduct, attention, and mental health).

Repeated screening compensates for underdetection. Developmental–behavioral problems are a "moving target" and thus require ongoing measurement. Although AAP policies identify specific ages when formal screening should occur (e.g., 9-, 18-, 24- or 30-mo), clinicians should not interpret AAP recommendations to mean that screening/surveillance can cease after 30 mo. Problems (such as language or school readiness) may still be emerging and will not be fully manifested in very young children. The AAP policy states that screening/surveillance should be provided at all well visits and is actively advocating for payers to reimburse for identification efforts with older children.

Although clinicians are often concerned about overidentification, most children with false-positive screens, although ineligible for special education services, have moderate delays in areas predictive of future school failure, that is, language, intelligence, and academic/preacademic skills, along with elevated psychosocial risk. Such children are in need of referrals to other types of intervention programs (e.g., Head Start, after-school tutoring, summer school, and quality preschool or daycare).

Use of accurate screens provides a focus for other well-visit activities. For example, screens relying on parents' concerns identify specific topics for developmental–behavioral promotion. The presence of delays prompts clinicians to conduct a particularly careful physical exam; repeat hearing and vision screening; thoughtfully observe parent–child interactions; take an especially detailed family medical/social history; and similar actions.

Deployment of quality screens provides decision support for the types of interventions needed, including whether clinical advice is sufficient, whether more intensive hands-on services are required, and/or subspecialty medical referrals are needed.

Surveillance refers to ongoing monitoring (tracking over time) of such issues as parental concerns, children's progress with milestones, psychosocial risk and resilience factors, providers' efforts to both detect and address problems, and follow-up regarding child/family outcomes. Surveillance also refers to use of clinical acumen in decision making via the incorporation of screening test results, child/family medical histories, and the physical exam. Repeated accurate screening also serves the tasks of surveillance, but with efficiency and effectiveness. Informal approaches to surveillance are known to be ineffective and of little benefit to families.

OVERCOMING LOGISTICAL CHALLENGES IN PRIMARY CARE EARLY DETECTION AND INTERVENTION

The lists of potential developmental-behavioral topics to be covered at well-child visits are extensive—far more than could be covered in the 14-18 min allotted for such encounters. It is essential to cull topics to those of greatest interest to parents so as to create "the teachable moment" wherein parents are primed to learn most from clinicians' recommendations. Solutions include posters in waiting rooms listing the range of topics on which providers can advise; previsit checklists on which parents indicate topics of interest (and which topics have already been covered in prior visits); and use of use quality screening tests eliciting parents' specific concerns and providing decision support, that is, when advice is probably sufficient vs when referrals are needed.

Clinicians are not always aware of the plethora of services available to families. Approaches to overcome this problem include creating a list of community programs to post in each exam room so that options are visible to parents and providers and encouraging non-medical services to provide prompt feedback on the status of referrals (e.g., establishing two-way consent forms for information sharing), evaluation results and recommendations. Implementing quality screens and patient education in practices requires thoughtful planning and generating enthusiasm among clinic staff who must aid in the process. Clinic flow templates and implementation worksheets are useful tools for establishing efficient implementation procedures.

Evidence-Based Tools

Table 16-1 shows a range of measures useful for early detection of psychosocial risk and resilience, and developmental–behavioral problems, including autism spectrum disorders. Because well-child visits are brief and have enormous agendas (physical exams, immunizations, anticipatory guidance, safety and injury prevention, developmental promotion, and developmental–behavioral screening/surveillance), tools relying on information from parents are ideal because they can be completed in advance of appointments, either online or in writing, whether at home, or while waiting for the encounter to begin. If tools are scored in advance of the patient encounter, clinicians can enter the exam room armed with needed information (e.g., parenting handouts, descriptions of services).

A Workable Process: Step-By-Step

The process of surveillance/screening as drawn from AAP policies is depicted in Figure 16-1 with a description provided in Table 16-2. Many tasks are staggered across visits so that each visit is only minimally burdened with measurement. Red flags are noted in Table 16-3 but are not a substitute for evidence-based screening. Asymptomatic children are those most in need of screening. Those with obvious symptoms simply need referral.

Table 16-2 mentions a range of tools by abbreviations as denoted Table 16-1. The Resources Section (Table 16-4) provides guidance on finding supportive information, practice tools, and the like.

Bibliography is available at Expert Consult.

Table 16-1 Print and Online Tools for Developmental–Behavioral Screening and Surveillance

The following chart is a list of measures meeting standards for screening test accuracy, meaning that they correctly identify, at all ages, at least 70-80% of children with disabilities while also correctly identifying at least 70-80% of children without disabilities. All listed measures were standardized on national samples, proven to be reliable, and validated against a range of diagnostic measures and diagnosed conditions. Not included are measures that fail to meet psychometric standards (limited standardization, absent validation, problematic sensitivity and specificity) such as Denver-II.

The first column provides publication information and the cost of purchasing a specimen set. The "Purpose and Description" column provides details about content and information on alternative ways, if available, to administer measures (e.g., waiting rooms). "Scoring" shows the types of results rendered. The "Accuracy" column shows the percentage of patients with and without problems identified correctly. The "Time Frame/Costs" column shows the costs of materials per visit, along with the costs of professional time (using an average salary of $60/hr) needed to administer each measure, but does not include time needed for generating referral letters. For parent self-report tools, administration time reflects not only scoring of test results, but also the relationship between each test's reading level and the percentage of parents with less than a high school education (who may or may not be able to complete measures in waiting rooms because of literacy problems and thus will need interview administrations).

SCREENS FOR PRIMARY CARE

BEHAVIORAL AND/OR DEVELOPMENTAL SCREENS RELYING ON INFORMATION FROM PARENTS	AGE RANGE	PURPOSE AND DESCRIPTION	SCORING	ACCURACY	TIME FRAME/COSTS
Ages & Stages Questionnaires, Third Edition (ASQ-3) (2009). Paul H. Brookes Publishing Co., Inc., P.O. Box 10624, Baltimore, MD 21285. (800-638-3775) ($295.00) *www.agesandstages.com*. **Training Options:** DVDs for purchase, case examples, and live training **Electronic Options:** See below	1-66 mo	**Purpose:** Screening and surveillance of developmental milestones **Description:** Parents indicate children's developmental skills on 30 items plus overall concerns. The ASQ has a different form (5-8 pages) for each age interval. Written at the 4th–6th grade level. Can be used in mass mail-outs for child-find programs. Manual contains detailed instructions for organizing child-find programs and includes activity handouts for parents. The ASQ-3 is available in English and Spanish; the ASQ-2 is also available in French and Korean with additional translations underway. The ASQ-3 Learning Activities kit is helpful for developmental promotion	Cutoff scores set at 2 SD below the mean, in 5 developmental domains; indicate need for referral or monitoring	**By age:** Sensitivity: 82-89% Specificity: 77-92% **By domain:** Sensitivity: 83% Specificity: 91% **By disabilities:** i.e., cerebral palsy, visual and hearing impairment: Sensitivity: 87%	Scoring time: 2 min Scoring cost: $2.40 Materials: ~$0.36-$0.48 **Total Self-Report: $2.76-$2.88** Interview Time: 12 min. Interview Cost: $14.40 Scoring/Materials: $2.76-$2.88 **Total Interview: $17.28**
Parents' Evaluations of Developmental Status (PEDS). (2013) PEDSTest.com, LLC, 1013 Austin Court, Nolensville, TN 37135 (615-776-4121) ($36.00) www.pedstest.com **Training Options:** offers through its website self-training/train-the-trainer support via downloadable slide shows with notes, case examples, pre-/posttest questions, FAQs, participant handouts, website discussion list (covering all screens), short videos, with some live training available **Electronic Options:** See below	Birth-8 yr	**Purpose:** Screening/surveillance of development/social–emotional/behavior/mental health via parents' concerns **Description:** 10 questions eliciting parents' (and providers') concerns in English, Spanish, Vietnamese and many other languages. Items written at the 5th grade level. Longitudinal Score and Interpretation Forms, assign risk levels, track decision making and offer specific guidance on how to address concerns. Provides screening, longitudinal surveillance, and triage for both developmental and behavioral/social–emotional/mental health problems. PEDS can be used in conjunction with the PEDS: DM (below) for compliance with AAP policies on screening and surveillance, i.e., eliciting and addressing parents' concerns and monitoring milestones	Identifies when to refer and what types of referrals are needed; advise parents; monitor vigilantly; screen further (or refer for screening); or reassure	**By age:** Sensitivity: 91-97% Specificity: 73-86% **By disabilities,** i.e., learning, intellectual, language, mental health, and autism spectrum disorders: Sensitivity: 71-87%	Scoring time: 1 min Scoring cost: $1.20 Materials: $0.39 **Total Self-Report: $1.59** Interview Time: 2 min Interview Cost: $2.40 Scoring/Materials: $1.59 **Total Interview: $3.99**

PEDS: Developmental Milestones (Screening Version) (2008) PEDSTest.com, LLC, 1013 Austin Court, Nolensville, TN 37135 (615-776-4121) ($275.00) *www.pedstest.com* **Training Options:** offers through its website self-training/train-the-trainer support via downloadable slide shows with notes, case examples, pre-/posttest questions, participant handouts, FAQs, website discussion list (covering all screens), short videos, with some live training available. The PEDS: DM manual includes extensive suggestions for training medical students, residents, and nurses **Electronic Options:** See below	Birth-8 yr	**Purpose:** Screening/surveillance of developmental and social–emotional/mental health milestones **Description:** PEDS-DM is designed to replace informal milestones checklists (such as key items from other measures) with evidence. It consists of 6-8 items at each age level. Each item taps a different domain: fine/gross motor, self-help, academics, expressive/receptive language, social-emotional. The PEDS: DM provides screening, triage, and surveillance via a longitudinal score form for tracking milestones progress. Written at the 2nd-3rd grade level and can be completed by self-report, interview, or administered directly to children. Forms are laminated and completed with a dry erase marker. Supplemental measures focused on AAP policy include the M-CHAT, Family Psychosocial Screen, Pictorial PSC-17, the SWILS, the Vanderbilt ADHD scale, and the Brigance Parent-Child Interactions Scale. When combined with PEDS, ensures full compliance with AAP policy. In English, Spanish, Taiwanese, and Portuguese, with other languages in process. The PEDS: DM manual and website contain developmental–behavioral promotion handouts	Pass/fail cutoffs tied to performance above and below the 16th percentile for each item and its domain	**By age:** Sensitivity: 70-94%; Specificity: 77-93% **By developmental domain:** Sensitivity: 75-87%; Specificity: 71-88%	Scoring time: 1 min Scoring cost: $1.20 Materials: $0.02 Total Self-Report: $1.22 Interview Time: 3 min Scoring/Materials: $1.22 Total Interview: $3.82 Direct Admin: 4 min Scoring/Materials: $1.22 Total Direct Admin: $6.10

Parent-report narrow-band screens (for social–emotional/behavioral/mental health, psychosocial risk, and autism spectrum disorder). These are valuable adjuncts in primary care and in other settings but only when preceded by a broadband screen. Narrowband tools should *not* be used as the sole measure of developmental–behavioral status).

NARROWBAND SCREENS RELYING ON INFORMATION FROM PARENTS	AGE RANGE	PURPOSE AND DESCRIPTION	SCORING	ACCURACY	TIME FRAME/COSTS
Modified Checklist for Autism in Toddlers (M-CHAT) (1999). Freely downloadable in multiple languages along with the Follow-up Interview at www.mchatscreen.com Also included in print in PEDS: Developmental Milestones. Commercial software vendors must pay a licensing fee **Training Options:** the site contains a guide to the needed follow-up interview for missed items, and houses research papers and reviews on autism spectrum disorder (ASD) screening **Electronic options:** see below	18-47 mo	**Purpose:** Screening for ASDs **Description:** Parent report of 23 yes-no questions written at 4th-6th grade reading level. Screens for ASD. Downloadable scoring template and Excel files for automated scoring. Requires a follow-up interview for failed items (which can be requested by referral sources). Available in multiple languages	Pass/fail scores based on failing at least 2 critical items, or 3 or more noncritical items	**By age and disability**: i.e., autism spectrum disorders**:** Sensitivity: 90%; Specificity: 99%	Scoring Time: 2 min Scoring costs: $2.40 Materials: $0.06 **Total (Self-Report): $2.46** Interview Time: 5 min (excluding follow-up on any failed items) Interview Cost: $6.00 Scoring/Materials: $2.46 **Total (Interview): $8.46**

Table 16-1 Print and Online Tools for Developmental–Behavioral Screening and Surveillance—cont'd

NARROWBAND SCREENS RELYING ON INFORMATION FROM PARENTS	AGE RANGE	PURPOSE AND DESCRIPTION	SCORING	ACCURACY	TIME FRAME/COSTS
Brief-Infant-Toddler Social-Emotional Assessment (BITSEA) (2006) Pearson/ Psych Corp, Inc.19500 Bulverde Road, San Antonio, TX 78259 (800-627-7271) ($113.75) www.pearsonassessments.com **Training Options:** none **Electronic Options:** None	12-36 mo	**Purpose:** Screening and surveillance of milestones in social–emotional and mental health **Description:** 42 item parent-report measure (with separate forms if clinical observation is needed). Identifies social–emotional/ behavioral. problems and delays in competence. Written at the 4th-6th grade level. Can be followed by the more detailed ITSEA. Available in Spanish, French, Dutch, Hebrew. Has a CD-ROM for ease of scoring and generating reports and referral letters	Cutpoints based on child age and sex show presence/ absence of problems and competence	**By age and disability:** i.e., internalizing, externalizing, and autism spectrum disorders: Sensitivity: 80-95% Specificity: 80%	Scoring Time: 3 min Scoring costs: $3.60 Materials: $1.56 **Total (Self-Report): $5.16** Interview Time: 6 min Interview Costs: $7.20 Scoring/Materials: $5.16 **Total (Interview): $12.36**
Infant-Toddler Checklist (2002). Paul H. Brookes Publishing Co., Inc., P.O. Box 10624, Baltimore, MD 21285. (800-638-3775) ($99.95) www.brookespublishing.com **Training Options:** live training and research support, downloadable slide shows, abstracts, videos, and references at http://firstwords.fsu.edu **Electronic options**: None	6-24 mo	**Purpose:** Screening and surveillance of language and social milestones **Description:** Parents complete the Checklist's 24 multiple-choice questions. Focuses on screening for language, social communication. Examiners are encouraged to observe child to verify parents' answers via brief observation. Reading level is ~ 3rd grade. Can serve as an entry point into the assessment-level CSBS and also as a monitoring tool. Does not screen for motor milestones. In English, Spanish, Slovenian, Chinese, and German	Cutoff scores for each domain: social, speech and symbolic	**By age and disability**: i.e., developmental disabilities: Sensitivity: 78% Specificity: 84%	Scoring time: ~10 min (by hand), ~3 with CD-ROM Observation time: ~5 min Scoring Costs: $3.60-$12.00 Observation Costs: $6.00 Material Costs: $0.12 **Total (Self-Report/Observation)**: $9.72-$18.12 Interview Time: 8 min Interview Costs: $9.60 Scoring/Materials + Observation: $9.72-$18.12 **Total Interview Costs**: $19.32-$28.72
Ages & Stages Questionnaires: Social–Emotional (ASQ:SE) (2002). Paul H. Brookes Publishing Co., Inc., P.O. Box 10624, Baltimore, MD 21285 (800-638-3775) ($225.00) www.agesandstages.com **Training Options**: training DVD live training, webinars, supporting research on website **Electronic options:** See below	3-66 mo	**Purpose:** Screening and surveillance of milestones in social-emotional and mental health **Description:** Companion measure to ASQ-3. ASQ:SE consists of 8 age-specific forms (each 4-6 pages long) with 22-36 items. Items focus on self-regulation, compliance, communication, adaptive functioning, autonomy, affect, and interaction with people. Readability is 5th-6th grade. Includes activities sheets for families. In English and Spanish	Single cutoff score indicating when a referral is needed	**By age and disability:** i.e., social–emotional problems: Sensitivity: 71-85% Specificity: 90-98%	Scoring Time: 2 min Scoring Cost: $2.40 Material Costs: $0.24-$0.36 **Total (Self-Report): $2.64-$2.76** Interview Time: 10 min Interview Cost: $12.00 Scoring/Materials:$2.64-$2.76 **Total (Interview):** $14.64-$14.76
Psychosocial Risk and Resilience Tools: Not all of the measures below are screens (meaning they do not provide definitive cutoffs) but instead assess a broad array of environmental risk and protective/resilience factors that may affect children's developmental/mental health trajectory—well before delays become obvious. Lack of resilience factors or presence of risk factors, even if all aspects of development are typical at the moment, serve as a call to lower thresholds for referral and to consider a wide-range of community services (e.g., Head Start, parent training, parent mental health programs/parents' own healthcare providers, social services)					

SURVEILLANCE TOOLS FOR RESILIENCE, RISK AND MENTAL HEALTH	AGE RANGE	PURPOSE AND DESCRIPTION	SCORING	ACCURACY	TIME FRAME/COSTS
Family Psychosocial Screen (FPS) (2000) Included within the AAP Pediatric Intake Form (http://www.brightfutures.org), within PEDS: Developmental Milestones, and freely downloadable at www.pedstest.com/TheBook/Chapter10 **Training Options:** none **Electronic Options:** none	Parent	**Purpose:** screening and surveillance of family psychosocial risk **Description:** A 2-page clinic measure of psychosocial risk factors associated with developmental problems, often used for clinic intake. More than 4 risk factors is associated with developmental delays. The FPS also includes: (a) a 4 item screen for parental history of physical abuse as a child; (b) a 6 item measure of parental substance abuse; (c) a 4 item screen for domestic violence; and (d) a 3 item measure of maternal depression. Can be used along with the Brigance Parent-Child Interaction Scale to view parenting risk and resilience. Readability is 4th grade. In English and Spanish	Refer/no refer to available community resources for each of the 4 screens' risk factors	By condition, i.e., parental depression, substance abuse, etc. Depression (3 items): Sensitivity: 100% Specificity: 88% Parental Substance Abuse (7 items): (a) alcohol abuse sensitivity ~90%; (b) drug abuse sensitivity ~88% Parent history of abusive punishment as a child (4 items): Sensitivity: 92-95%; Specificity: 87-92%	Scoring Time: 3 min Scoring Cost: $3.60 Material Costs: photocopied: $0.12 Laminated: $0.00 **Total (Self-Report): $3.60-$3.72**
Brigance Parent-Child Interaction Scale (BPCIS) (2007) PEDSTest.com, LLC. The BPCIS is included in PEDS: Developmental Milestones and in the Brigance Infant and Toddler Screen. It can be freely downloaded at: http://www.pedstest.com/TheBook/Chapter10 **Training Options:** none **Electronic Options:** none	0-30 mo	**Purpose**: Surveillance of parenting behaviors associated with resilience vs psychosocial risk **Description:** Administered by parent-self report or examiner observation, the 18-19 multiple choice items tap whether parents read and talk with their child, enjoy talking with their child, and perceive him/her as interested in communication, whether parents actively teach their child new things, etc. Certain items are associated with resilience while others are associated with accumulating delays (which start to become visible at 6 mo of age and are striking by 12-18 mo)	Item analysis—discrete sets of items reflect resilience factors associated with typical development while others items reflect limited resilience associated with future or current delays	Not applicable	Scoring Time: 1 min Scoring Costs: $1.20 Materials ~$0.06 **Total (Self-Report): $1.26** Interview/Observation Administration time: ~5 min Interview Admin Costs: $6.00 Materials/Scoring ~$1.26 **Total (Direct Admin): $7.26**
Strengths and Difficulties Questionnaire (SDQ) http://www.sdqinfo.org freely downloadable in multiple languages **Training options:** none **Electronic options:** none	4-17 yr	**Purpose:** Resilience and psychosocial risk for mental health/social–emotional, behavioral skills **Description:** 25 items (youth self-report vs parent or teacher report) tapping positive and negative attributes. Generates indicators for conduct problems, hyperactivity, emotional symptoms, peer problems and prosocial behavior. Produces a total strengths vs total difficulties score. Guidance is available on how to aggregate results for epidemiologic and needs-assessment studies. Cross-cultural research and translations are abundant and norming studies have been conducted in Great Britain, the United States and otherwise in European countries	Comparison of factors	Not applicable	Scoring Time: 5 min Scoring Cost: $6.00 Materials: ~$0.12 **Total (Self-Report): $6.12** Interview time: ~5 min Interview Admin costs: $6.00 Materials/Scoring: ~$0.12 **Total (Direct Admin): $12.12**

Table 16-1 Print and Online Tools for Developmental–Behavioral Screening and Surveillance—cont'd

SCREENS FOR OLDER CHILDREN (These screens focus on academic skills and mental health, including ADHD screening)					
SCREENS FOR OLDER CHILDREN	**AGE RANGE**	**PURPOSE AND DESCRIPTION**	**SCORING**	**ACCURACY**	**TIME FRAME/COSTS**
Safety Word Inventory and Literacy Screener (SWILS). From PEDSTest.com, LLC with items courtesy of Curriculum Associates, Inc. The SWILS is included in PEDS: Developmental Milestones (PEDS:DM) and is freely downloadable at: http://www.pedstest.com/TheBook/Chapter9 **Training Options:** none **Electronic Options:** none	6-14 yr	**Purpose:** Screening and surveillance of academic skills **Description:** Children are asked (by parents or professionals) to read 29 common safety words (e.g., high voltage, wait, poison) aloud. The number of correctly read words is compared to a cutoff score. Results predict performance in math, written language, and a range of reading skills. Test content may serve as a springboard to injury prevention counseling and can be used to screen for parental literacy. Because even non-English speakers living in the United States need to read safety words in English, the measure is only available in English	Single cutoff score by age, indicating the need for a referral	**By age/academic deficits:** Sensitivity: 73-88% Specificity: 77-88%	Scoring Time: 1 min Scoring Costs: $1.20 Materials ~$0.06 **Total (Self-Report): $1.26** Administration time: ~7 min Admin/Scoring Costs: $8.40 Materials/Scoring ~$1.26 **Total (Direct Admin): $9.66**
Pediatric Symptom Checklist (PSC) (1991). Freely downloadable in multiple languages in its 30 question version at http://psc.partners.org **The Pictorial PSC** is useful with low-income Spanish and English speaking families and is included in its 17 item factorable version in PEDS: Developmental Milestones and is available at http://www.pedstest.com/TheBook/Chapter9 **Training Options:** none **Electronic Options:** see below	6-18 yr	**Purpose:** Screening and surveillance of emotional/mental health, and conduct. Serves as a necessary prescreen for sorting attention problems from competing conditions **Description:** Administered by youth/parent self-report or by interview. The PSC/Pictorial PSC are 35 short statements of problem behaviors capturing various mental health challenges. The PSC-17/Pictorial PSC-17 are 17 item versions producing cutoffs for attentional, internalizing (meaning depression or anxiety) and externalizing problems (conduct, impulsivity, etc.) Readability is ~2nd grade. In English, Spanish, Portuguese, Chinese, Dutch, Filipino, French, Somali, and several other languages	For the PSC, a single refer/nonrefer score; for the PSC-17/Pictorial PSC-17, cutoffs for attention, internalizing, and externalizing factors	**PSC/Pictorial PSC by disability:** i.e., mental problems of any kind, across numerous studies: Sensitivity: 80-95% Sensitivity: 68-100% **PSC-17/Pictorial PSC-17 by specific disability:** i.e., ADHD: Sensitivity: 58% Specificity: 91% Internalizing Disorders: Sensitivity: 52-73% Specificity: 74% Externalizing Disorders: Sensitivity: 62% Specificity: 89%	Scoring time: 3 min Scoring Cost: $3.60 Materials ~$0.06 **Total (Self-Report): $3.66** Interview Time: 3 min Interview Cost: $3.60 Materials/Scoring: $3.66 **Total (Interview): $7.26**
CRAFFT (Car, Relax, Alone, Forget, Friends, Trouble): (2009). Freely downloadable from the Center for Adolescent Substance Abuse Research http://www.ceasar-boston.org **Training options:** none **Electronic options:** none	Adolescents (11-21 yr)	**Purpose:** To identify substance use (tobacco, alcohol or other drug abuse) in adolescents **Description:** self-/youth-report questionnaire that contains 3 initial screening questions (A1, A2, A3). If the first 3 questions are all answered "no," then providers should routinely ask 1 more question (B1). If 1 or more of the first 3 screening questions is positive/answered "yes," then the provider should ask 6 more questions (CRAFFT: B1, B2, B3, B4, B5 and B6). If the CRAFFT score is 0 or 1 (0 or 1 item answered "yes"), then give brief advice only. If the CRAFFT score is >2, then this is a positive screen and a brief assessment is needed	For scoring, refer to "description" Note: The AAP has published a recommended algorithm for substance abuse screening, assessment and intervention. Must be completed by youth confidentially	Sensitivity: 76-93% Specificity: 76-94% (positive predictive value [PPV] 29-83%) (negative predictive value [NPV] 91-98%) However, there is no cross cultural data (similar to the PSC and Pictorial PSC)	Scoring time: 1-2 min Scoring cost: $1.20-$2.40 Materials ~$0.06 **Total (Self-Report): $1.26-$2.46** Interview time: 3 min Interview cost: $3.60 Materials/Scoring: $3.66 **Total (Interview):** $4.86-$6.06 but higher if further counseling and intervention is needed

ELECTRONIC RECORDS OPTIONS FOR SCREENING AND SURVEILLANCE WITH QUALITY TOOLS

Essential definitions are:

- Tablet PC—approaches that typically require a stylus to select among multiple-choice answers only;
- Keyboards—approaches enabling users select multiple-choice responses but also type in text-based answers to questions
- Touch-screens applications—these often allow parents to listen to questions and response options and then touch a simple response box (e.g., yes/no) thus reducing literacy demands;
- Online—meaning hosted on a website and thus requiring an Internet connection, preferably high speed;
- PDA—personal digital assistant such as a Palm Pilot or Blackberry usually requiring users to be online, with or without a keyboard
- CD-ROM—offline but still electronic, and requiring installation on the user's computer;
- Parent Portal—online applications wherein parents can complete measures but do not see results; instead, these are sent to a different office computer for retrieval/inclusion in electronic records
- Telephony—automated calling, often along with appointment reminder systems through which multiple-choice screens can be administered;
- Data Aggregation—almost all electronic applications create a database either online or on individuals' computers (in the case of CD-ROMs) where all administered screens can be viewed, overall results summarized, etc. Some web-based scoring services provide exported files; (e.g., Excel compatible) to allow users to view overall results. In all such applications, an administrator of multiple sites can view all results
- Webcasts/webinars—These are training options online, either live on a specific day and, eventually constantly available on publishers' websites.

COMPANY/OFFERINGS	TRAINING/SUPPORT OPTIONS	DESCRIPTION AND PRICING
CHADIS: http://www.chadis.com **ASQ, M-CHAT, PSC, and other measures online for touch-screen, tablet PCs, keyboards, telephony and parent portal methods). Spanish language applications coming soon**	Downloadable guides, live training at exhibits, and other training services on request	CHADIS includes decision support for more than 75 both diagnostic and parent/family focused measures, such as the Vanderbilt ADHD Diagnostic Rating Scale, and various parent and adolescent depression, substance abuse, domestic violence and other inventories. CHADIS offers integration with existing electronic healthcare records (EHRs), works with a range of equipment/applications, and automatically generates reports. Pricing is via site license and ~$695 per year per full-time provider. Includes options for Maintenance of Certification (MOC), quality improvement (QI) credit, and e-chapters for clinicians
PEDS Online: http://www.pedstest.com/online PEDS, PEDS: DM, M-CHAT online (for keyboards) in English and Spanish	Slide shows, website FAQs, email support, online videos, discussion list	This site offers PEDS, PEDS:DM, and the MCHAT for keyboard applications (allowing for actual comments from parents). Offers a parent portal (wherein families do not see the results). Scoring is automated as are summary reports for parents, referral letters when needed, and ICD-9/procedure codes. In English and Spanish. Health Level Seven (HL7)/Health Insurance Portability and Accountability Act (HIPPA)/Family Educational Rights and Privacy Act (FERPA) compliant integration with electronic records is available as is data export and aggregate views of records. $2.00-$2.75 per encounter (depending on volume)
Patient Tools: http://www.patienttools.com (M-CHAT, ASQ, ASQ: SE and other measures online for tablet, i.e., touch-screen PCs)	Webcasts/webinars, live support by phone, email	Patient Tools offers the ASQ (with audio option), ASQ: SE (with audio option), MCHAT, PEDS (in a survey version, i.e., closed-ended questions), PSC, the Vanderbilt ADHD Scales and a wide range of behavioral/mental health measures in multiple languages for adolescents and adults. A practice-based approach provides access in the office via dedicated Survey Tablet equipment, wireless tablet PCs and kiosk PC; or online from home with results available in the office. Access fees are $58.00/mo for ongoing hosting, data storage, reporting, custom programming, telephone technical and installation support. Uses client's PCs or alternately Survey Tablet equipment, including rentable docking stations, lease-purchasing arrangements, or software purchase ($1,525) plus hosting and installation ($58.00/mo) with additional licensing fees for some measures
Ages and Stages-3 and ASQ: SE: http://www.ASQonline.com **Online administration and separately on a CD-ROM for offline administration with keyboards and tablet PCs**	Live training, online training	Web-based management system offers automated scoring, reporting, referral tracking, and customizable letters for parents/providers for ASQ-3 and ASQ: SE. ASQ Pro is designed for single-site programs ($149.95 annual subscription, plus quarterly billing for screens used) and ASQ Enterprise is designed for multisite programs ($499.95 annual subscription, plus quarterly billing for screens used). Online questionnaire completion available through ASQ Family Access ($349.95 annual subscription). ASQ Family Access provides secure, customizable website for parent completion of questionnaires, i.e., a parent portal ($349.95 for an annual subscription plus $79.95 for annual support)

Table 16-2 Annotated Description of Screening/Surveillance in Primary Care

A. **Elicit Parents' Concerns**
At every visit, it is crucial to identify the parent/patient agenda, preferably prior to the encounter, so that clinicians can best prepare for the topics at hand. Informal questions to parents are rarely effective at eliciting their unique issues and do not render the decision support needed to discern which concerns are predictive of problems and which can be addressed with information and monitoring. It is best to use a standardized, validated screening/surveillance measure such as PEDS which is also known to reduce problematic "oh, by the way" concerns, increase the likelihood of attendance at subsequent well-visits, and encourage referral uptake.

B. **Measure/Monitor Children's Skills**
1. Use a broadband milestones-focused screen such as the ASQ or PEDS : DM starting at 6-9 mo and at subsequent well-visits.
2. Use an autism-specific screen such as the M-CHAT at 18 and 24 mo and whenever clinical observation or parents' concerns are worrisome. The requisite M-CHAT Follow-Up Interview (used after a failed M-CHAT) can become a request to referral sources.

Note 1: If using a broadband milestones-focused screen such as the ASQ that does not cover social–emotional/mental health skills, additional screens (e.g., ASQ : SE) should be administered when problems arise and otherwise periodically. When time is limited, referral sources can assist with further evaluations.
Note 2: Use of accurate parent-completed tools prior to the visit is particularly efficient (e.g., from home via electronic screening services, on waiting or exam room computers, paper-pencil, or by staff/clinician interview). As with eliciting parents' concerns, having results available before the encounter gives clinicians an opportunity to prepare referral and/or patient education information.

C. **Measure/Monitor Psychosocial Risk Factors**
At the initial/intake visit (typically the 1st wk of life), a measure such as the Family Psychosocial Screen (FPS) is useful for identifying psychosocial and other risk factors (e.g., substance abuse, domestic violence, housing and food instability, parents' education levels, parental mental health and social support). Four or more risk factors, in the absence of intervention, generally lead to substantial declines in developmental–behavioral status. The FPS also contains a 3-item parental depression screen that should be readministered twice in the 6-15 mo age range to identify and address issues with postpartum dysthymia.

D. **Measure/Monitor Parent–Child Interactions (Resilience Factors)**
Protective (also called resilience) factors are the positive parent–child interactions that promote developmental and behavioral skills (e.g., when parents actively and age-appropriately teach children new things, label objects of interest, share books, and converse with their child [including back-and-forth sound play in infancy, playing peek-a-boo, etc.]). Positive interactions often eclipse psychosocial risk factors and so it is helpful to measure both at the same time. A dearth of positive interactions takes a long-term toll on developmental–behavioral status with marked differences appearing as early as 12-mo of age. Although clinicians sometimes have opportunities to observe parent–child interactions, it is often easier to ask parents to complete a measure such as the Brigance Parent-Child Interactions Scale (BPCIS). Administration at 6 and again at 15 mo is recommended, along with parenting guidance and referrals for parent training when parents have not benefited from in-office advice.

E. **Identify/Update Family and Child Medical History and Biologic Risk Factors**
Child's Medical History: Note in utero exposure to teratogenic/harmful substance, Apgar score less than 5 at 5 min, late or moderate preterm (>32 0/7 to 36 6/7 wk gestational age), very preterm (<32 wk gestational age, low birthweight (<2,500 g), very-low birthweight (<1,500 g), small for gestational age, in utero growth retardation; child's history of: obesity, diabetes, or hypertension, congenital hydrocephalus, meningomyelocele, interventricular hemorrhage (grade III or IV), respiratory distress syndrome, anoxic brain injury, encephalopathy, genetic, metabolic or neurodevelopmental disorder with a high probability of a developmental delay, failure to thrive, iron-deficiency anemia, elevated blood lead level, vision or hearing impairment, HIV, congenital heart disease, obstructive sleep apnea, seizure disorder, etc.
Family Medical/Developmental History: Note any family history of language impairment, learning or intellectual disabilities, autism spectrum disorders, motor disorder, fragile X syndrome, attention-deficit/hyperactivity disorder, mental illness including anxiety disorder, major depression, bipolar disorder, history of deafness, genetic or metabolic disorders, cataract, retinoblastoma, retinal dysplasia, or glaucoma.
In most states, children are automatically eligible for IDEA services if they have a diagnosed condition involving biologic/medical risk factors. In some states, IDEA programs serve children whose parents are mentally ill, intellectually disabled, as well as children in foster care because of a history of abuse or neglect.

F. **Conduct a Careful Physical Exam**
Identify any chronic respiratory or allergic illness, recurrent otitis, head trauma, and sleep problems including symptoms of obstructive sleep apnea. Attend to known symptoms of developmental–behavioral problems, including growth parameters, head shape, and circumference, especially in light of prior visits (e.g., failure to thrive, microcephaly or markedly decelerating head circumference, markedly accelerating head circumference or macrocephaly), facial and other body dysmorphology symptomatic of genetic conditions, eye findings (e.g., cataracts in various inborn errors of metabolism), vascular markings, testicular volume, and signs of neurocutaneous disorders (e.g., >6 café-au-lait spots in neurofibromatosis, hypopigmented macules in tuberous sclerosis), Lisch nodules, ash leaf macules, etc. Neurodevelopmental assessment should include muscle strength, joint laxity, tone, presence of abnormal reflexes, and disturbance of movement.
Focus carefully on physical findings suggestive of abuse or neglect and ensure prompt referrals to social work services.
Newborn hearing screening is essential but even the asymptomatic need follow-up with otoacoustic emissions (OAE) beginning at 6-mo of age and thereafter, as well as tympanometry to evaluate of middle ear pathology. Failed OAEs regardless of middle ear status require an axiomatic referral to an audiologist.
Assess vision at every visit: (a) Abnormal red reflex (may indicate cataract, glaucoma, retinoblastoma, retinal abnormality, or strabismus, or unequal or high refractive error); (b) abnormal ocular alignment (i.e., strabismus) or asymmetrical corneal light reflex; (c) pupillary asymmetry of ≥1 mm (suggestive of neurologic condition); (d) corneal asymmetry (suggestive of glaucoma); (e) unilateral ptosis or other lesions obstructing the visual axis (e.g., eyelid hemangioma), which may cause amblyopia; and (f) nystagmus. For children 3-4 yr of age, measures of visual acuity are needed for which the Lea Symbols are helpful because letter naming is not required. At age 5-6 yr, Snellen Eye Charts can be used. Prompt referral to a pediatric ophthalmologist is warranted when acuity is less than 20/40 in children ages 3-5 yr, or 20/30 in children >6 yr.
Lead screening should be provided whenever developmental–behavioral problems arise, but preferably for all children. Lead screening should be repeated at several points during the 0-6 yr age range. Children living in older homes, near busy streets, with pica, or recently immigrated are at particular risk, as are those who play with adult makeup.
Many of the above findings will automatically qualify children for IDEA Part C programs (birth-3) and so referral for early intervention should be axiomatic in such cases.

Table 16-2 Annotated Description of Screening/Surveillance in Primary Care—cont'd

G. **Provide Developmental–Behavioral Promotion**

Whether or not screening/surveillance identifies problems, parents always need suggestions for what to do at home. The specifics of their concerns should be addressed with parenting information, advice on age-appropriate activities, and anticipatory guidance focused on how developmental changes affect health and safety (e.g., a baby about to crawl will find, mouth, and probably swallow small objects left under furniture). All parents need to be encouraged to promote their child's language and preacademic/academic development. This is most easily accomplished with written patient education materials, by encouraging parents to visit websites with quality information, participating in Reach and Read, or by parent training classes, group well visits, or social work services. A well-organized system for filing and retrieving parent-focused materials is essential (see Table 16-3 for resources). Follow up with families, in 6-8 wk to assess the effectiveness of promotion activities, especially in-office advice about behavior and social skills. If less than successful, encourage parents to engage in more intensive services (e.g., parenting classes, family therapy). Information and referral resources are listed under the Resources section for this chapter.

H. **Interpret Results, Explain Findings, Decide on Any Needed Referrals**

Refer those at psychosocial risk and those with an absence of protective factors for Head Start/Early Head Start, quality daycare, or evidence-based parent-training programs. For all children with positive screens, refer to IDEA programs. Additionally, refer to autism specialty clinics if indicated.

Consider whether medical subspecialty referrals are needed. Electroencephalograms and neuroimaging are not routinely indicated but might be used if there is clinical suspicion of a seizure disorder, hydrocephalus, micro- or macrocephaly, encephalopathy, neurofibromatosis, tuberous sclerosis, brain tumor, or other neurologic problem (not including autism). Extreme handedness at an early age and persistence of fisting after 4 mo is another indicator of potential neuron migration disorders requiring imaging. Uncommonly, surveillance may indicate a need for additional metabolic screens, such as serum electrolytes and glucose, venous blood gas, serum ammonia, urine glycosaminoglycans, endocrine screens (e.g., thyroid-stimulating hormone, free thyroxine), creatinine kinase (CK), genetic testing (chromosomal analysis, DNA for fragile X, etc.), or screens for an infectious disease (e.g., HIV antibody testing, TORCH [toxoplasmosis, other agents, rubella, cytomegalovirus, herpes simplex] infection testing). Because of the need to discern which tests are needed, referral to a developmental–behavioral or neurodevelopmental pediatrician is wise.

Gather referral information and then explain results to families. Sit down with them and describe referrals in a positive light (e.g., "There is much we can do to help."). Avoid diagnostic labels because in all cases, further evaluation will be provided by referral services. Use euphemisms (e.g., "seems behind others," "seems to be having difficulty with") but use language strong enough that parents will take your concerns seriously. If at all possible, provide a take-home summary report. Most online screening services generate these automatically.

I. **Document Findings and Make Referrals**

A carefully constructed well-visit age-specific encounter form should have space to indicate measures administered and results. A longitudinal problem checklist should be used to briefly document results over time, intervention recommendations, (and will also help identify which measures are needed and when). Billing and coding for optimal reimbursement is essential (in many states, developmental–behavioral screening when coded properly, incurs separate reimbursement). A referral letter is also needed that can be shared with other programs. Be sure to document not only screens administered, results and observations but also health, hearing, and vision status; IDEA requires such information before evaluating children further. Online screening services generate referral letters and thus save a great deal of practice time and expense. If at all possible, make appointments for families because this greatly increases uptake. For examples of age-specific encounter forms, referral letters, and take-home parent summary reports, see www.pedstest.com/thebook.

J. **Ensure a Medical Home**

Children with health and developmental–behavioral problems often receive splintered care with little oversight from primary care providers who, in fact, should be the center of care coordination. Many families do not seek services in a timely manner and so it is critical to establish follow-up dates (e.g., on a longitudinal problem checklist) to determine whether recommendations were followed and whether additional screening or other encouragement is needed.

Establishing communication mechanisms with IDEA and other referral services is helpful so that personnel offer prompt updates on whether appointments were kept, results of further testing, and eligibility for services. Be aware that some referrals will not result in service eligibility due to deficits of insufficient severity. Note that in some, but not all states, IDEA programs for the birth-3 yr age-range can provide ongoing monitoring of ineligible children and suggest to parents other helpful resources. Prompt feedback on the issue of eligibility and ongoing monitoring is needed so that clinicians can refer to other types of intervention programs (e.g., quality daycare, Head Start, parenting training).

In any case, make sure to collaborate with non-medical services by establishing 2-way consent forms for sharing information. Clinicians should also identify communication preferences (e.g., by email, fax, or telephone [including available hours]) and the kind of information to be sent (e.g., evaluation reports, status updates, individual educational plans). Collaboration is facilitated if providers agree to advise intervention programs about medical conditions and medical interventions that may be needed at school.

Table 16-3 Red Flags in Developmental Screening and Surveillance

These indicators suggest that development is seriously disordered and that the child should be promptly referred to a developmental or community pediatrician.
Note: Most children do not have "red flags" and thus require quality screening to detect any problems.

POSITIVE INDICATORS (THE PRESENCE OF ANY OF THE FOLLOWING)
Loss of developmental skills at any age
Parental or professional concerns about vision, fixing, or following an object or a confirmed visual impairment at any age (simultaneous referral to pediatric ophthalmology)
Hearing loss at any age (simultaneous referral for expert audiologic or ear, nose, and throat assessment)
Persistently low muscle tone or floppiness
No speech by 18 mo, especially if the child does not try to communicate by other means such as gestures (simultaneous referral for urgent hearing test)
Asymmetry of movements or other features suggestive of cerebral palsy, such as increased muscle tone
Persistent toe walking
Complex disabilities
Head circumference above the 99.6th centile or below 0.4th centile. Also, if circumference has crossed 2 centiles (up or down) on the appropriate chart or is disproportionate to parental head circumference
An assessing clinician who is uncertain about any aspect of assessment but thinks that development may be disordered

NEGATIVE INDICATORS (ACTIVITIES THAT THE CHILD CANNOT DO)
Sit unsupported by 12 mo
Walk by 18 mo (boys) or 2 yr (girls) (check creatine kinase urgently)
Walk other than on tiptoes
Run by 2.5 yr
Hold object placed in hand by 5 mo (corrected for gestation)
Reach for objects by 6 mo (corrected for gestation)
Point at objects to share interest with others by 2 yr

Table 16-4 Resources for Developmental–Behavioral Screening/Surveillance in Primary Care

DEVELOPMENTAL–BEHAVIORAL PROMOTION AND PARENT TRAINING
Kids' Health
From the Nemours Foundation, this site has a well-visit guide for each age, anticipatory guidance information, and an easily searchable database for handouts (in English and Spanish) on health and safety, emotional and social development and positive parenting for babies through adolescence.
Reach Out and Read
Offers parenting handouts on how to share books, literacy milestones, and guidance for professionals. Tabs within the site include: Parents and Educators Home, Importance of Reading Aloud, Literacy Milestones, Reading Tips, Books for Children, and Books for Parents.
American Academy of Pediatrics (Information for Families)
The AAP has numerous handouts that can be downloaded for free and available in multiple languages. Provides information on a variety of topics including health conditions, safety and prevention, mental health issues from birth through adolescence.
American Academy of Child and Adolescent Psychiatry
AACAP was one of the first professional organizations to develop handouts for families. These are freely downloadable and cover a wide range of topics as divorce, sleep problems, specific mental health diagnoses, help for military families, and how and where to find a psychiatrist. Handouts are written in many different languages including Spanish, Malaysian, Urdu, Arabic, Icelandic, Polish, and Hebrew. Other site research reviews for professionals, video clips, and links to other resources.

REFERRAL LINKS
American Academy of Pediatrics: Find a Pediatrician
Helps locate developmental–behavioral, neurodevelopmental, general and other subspecialty pediatricians.
Individuals with Disabilities Education Act
Provides links to state, regional and local early intervention programs under the Individuals with Disabilities Education Act, and testing services for young children with suspected or known to have disabilities go to
Early Head Start and Head Start
Provides links to local programs including services for migrant workers, tribal councils, etc.

INTERVENTION SERVICES FOR OLDER CHILDREN
To refer children 3 yr of age and older for evaluations, contact the school district's department of psychology or special education.
For after school/tutoring programs, check with the child's school of zone, and see the websites of the **Boys and Girls Club** and the **YWCA.**

TRAINING AND IMPLEMENTATION PLANNING
Medical Home Initiative
From the AAP and focused on coordinated care for children with special healthcare needs, the site has training materials, rating scales, an e-mail announcement list for providers, how-to information, etc. Medical Home also sponsors several conferences each year.
Harvard University
Includes a helpful video showing providers who, although reluctant to try quality screening, found use of tools far more sensitive and less than time-consuming. The site also provides a helpful implementation guide.
PEDStest.org
Includes downloadable implementation planning forms, workflow charts, two-way consent forms, longitudinal problem checklists, age-specific encounter forms, training guides, slide shows, freely downloadable risk and resilience measures, mental health and academic screens for older children, videos offering a rationale for screening, information about tools, guidance on billing and coding, and links to parenting resources in multiple languages.

Chapter 17

Childcare: How Pediatricians Can Support Children and Families

Laura Stout Sosinsky and Walter S. Gilliam

In the United States, 61% of all children younger than 5 yr—12.5 million children—were in regular childcare in 2011. Large proportions of young children are in childcare at all ages, with more children entering care as they get older; the majority of children 3 yr of age or older are in regular childcare. Young children of employed mothers spend on average 36 hr per wk in a childcare arrangement.

Childcare is affected by many factors, which derive from family demand, childcare supply, and child and family policy. With increasing movement of mothers into the workplace across the globe, the prime reason most families use childcare is to support maternal employment. At childbirth, unpaid maternity leave is the typical solution among U.S. mothers. The U.S. federal leave program allows for 12 wk of unpaid job-protected leave during pregnancy or after childbirth, but only covers approximately 50% of the workforce, as companies with <50 employees, part-time employees, and those working in informal labor markets are exempt. Four states and the District of Columbia have passed paid family leave laws. In part because of the financial burden of an unpaid maternity leave, many mothers return to work and their children begin childcare very young, sometimes in the 1st few wk after birth. In a 2000 Family and Medical Leave Act survey, only 10% of respondents reported taking more than 60 days for maternity leave. Approximately 44% of mothers in 2005-2007 were working by the time their first child was 3-4 mo of age, and approximately 63% of mothers were working by the time their first child was 12 mo of age. Some mothers face work requirements if they are receiving public benefits given the reforms to welfare passed by Congress in 1996. Many mothers feel strong financial motivation or even pressure to work, especially in single-parent households, or have strong incentive to work for short- and long-term financial security, interest and preference, or all of these. Maternal employment is not the only factor driving childcare use, as young children of unemployed mothers spend on average 21 hr per wk in childcare. Many parents want their children to have childcare experiences for the potential benefits early learning environments can give to their children, particularly preschoolers. Given these realities, childcare quality is of great concern, yet the quality of childcare and early education environments varies widely and the supply of high-quality childcare is largely deemed inadequate.

PROVISION AND REGULATION OF CHILDCARE IN AMERICA

Childcare Settings

Childcare settings vary widely and fall into 4 broad categories, here listed from the least to the most formal:

- Relative care;
- In-home nonrelative care such as nannies, babysitters, or au pairs;
- Family childcare, in which the caregiver provides care in her own home for up to 6 young children often including children of mixed ages, siblings, or the provider's own children; and
- Center-based care, provided in nonresidential facilities for children grouped by age.

Parents more often utilize home-based care for infants and toddlers, partly because of greater preference, flexibility, and availability, and sometimes because of lower cost. Use of center-based childcare is greater among preschoolers (children 3-5 yr old). Childcare centers and early education programs are administered by a wide array of businesses and organizations, including for-profit independent companies and chains, religious organizations, public and private schools, community organizations, cooperatives, and public agencies. Preschool programs (e.g., Head Start, prekindergarten) also may play an important role in childcare. Although early education programs may have a greater focus on educational activities and often only provide limited hours of care per days, the health and safety issues involved with preschool programs are similar to those presented by other group childcare settings.

Childcare Licensing, Regulation, and Accreditation

Licensing and regulatory requirements for the most part mandate basic health and safety standards, such as sanitary practices, child and provider vaccinations, access to a healthcare professional, and facilities and equipment safety, as well as basic structural and caregiver characteristics, such as the ratio of children to staff, group sizes, and minimum caregiver education and training requirements. Most childcare centers and preschools and many family daycare providers are subject to state licensing and regulation. As of this writing, with the exception of Idaho, all states regulate centers, as does the District of Columbia (for the most recent data, see http://www.naralicensing.org/Licensing). Most states also regulate family childcare providers, although some states only license specific types of family childcare homes, and 3 states do not license these providers at all (Idaho, Louisiana, and New Jersey). Seven states (Arizona, Idaho, Louisiana, New Jersey, Ohio, South Dakota, and Virginia) do not license small family childcare homes, and 11 states (Arkansas, Idaho, Kentucky, Louisiana, Maryland, Maine, North Carolina, New Jersey, Vermont, Washington, and Wisconsin) and the District of Columbia do not license large/group family childcare homes. Louisiana has a registration process for family childcare homes with no more than 6 children, but registration is only required when the provider cares for children subsidized by the federal Childcare and Development Fund (which assists low-income families receiving temporary public assistance, or those needing childcare in order to work or receiving training to transition off of public assistance). New Jersey has a voluntary registration process for family childcare homes that is operated by childcare resource and referral agencies in the state.

Many providers are legally exempt from licensing standards. Exemptions for various types of programs vary state to state. The smallest homes (3-4 children in care) are typically license-exempt, encompassing relative, friend, and neighbor caregivers as well as babysitters, nannies and au pairs. These providers fall outside of any regulatory scrutiny, and some may not even think of themselves as offering "childcare"; 31% of 9 mo olds and 22% of 2 yr olds may be in small home-based care settings (3 or fewer children). Fewer are cared for in large home-based settings (4 or more children), typically by nonrelatives. Small family childcare homes are exempt if there are a small number of children in care in 26 states, and large/group family childcare homes are exempt if they are open part-day in 11 states. Unlike exemption rules for homecare providers, which typically are based on size, centers are often exempted if overseen by other organizations such as schools, churches, or local governments, and thus have some external oversight. Many of these entities provide part-day or part-week Head Start or preschool programs, and about half of the states also explicitly exempt such part-time programs. Just 9% of 9 mo olds and 17% of 2 yr olds were cared for in centers. In contrast to care for 4 yr olds (when more than half of children are in center care), few centers caring for younger children were exempt from licensing (35% of centers caring for 4 yr olds were not licensed in contrast to 2% of centers caring for 2 yr olds).

Homes and centers that fall under state licensing guidelines face very different requirements. Size differs greatly between the 2 types of contexts, and such size differences are built into regulations in terms of the maximum number of children that can be cared for in a group and the number of adults that must be present. The most common state-required maximum group size in centers is 8 for infants, 12 for toddlers, and 20 for preschoolers; centers may have numerous classrooms of these sizes. For centers, regulations explicitly state an allowable ratio of children to adults. The most common ratios are 4 : 1 for infants, 6 : 1 for toddlers, and 10 : 1 for preschoolers, meaning that typically there would be 2 adults in a group. States license homes in 2 categories, small and large, with typical maximums of 6 and 12 in the 2 categories (including the provider's own children). More than three-quarters of licensed homes fall within the small category. Thus the total size of a typical home is smaller than just 1 classroom in a center. States less often explicitly lay out child-to-adult ratios for homes, given that many homes involve 1 provider caring for all of the children. Some states restrict the number of younger children that may be in care, or explicitly provide ratios (especially for large homes), although these restrictions vary greatly across states.

Health and safety conditions may be unsatisfactory in unlicensed settings. In most states, licensing and regulatory standards have been found to be inadequate to promote optimal child development, and in many states standards are so low as to endanger child health and safety. Therefore, even licensed providers may be providing care at quality levels far below professional recommendations. A small portion of providers become accredited by National Association for the Education of Young Children (NAEYC), National Association for Family Child Care (NAFCC), or other organizations by voluntarily meeting high-quality, developmentally appropriate, professionally recommended standards. The accreditation process goes far beyond health and safety practices and structural and caregiver characteristics to examine the quality of child–caregiver interactions, which are crucial for child development, as described in the next section. Evidence indicates that childcare programs that complete voluntary accreditation through NAEYC improve in quality and provide an environment that better facilitates children's overall development. Only 10% of childcare centers and 1% of family childcare homes are accredited; this is partly the result of a lack of knowledge, resources, and incentives for providers to improve quality, but it may also be partly because of expenses providers incur in the process of becoming accredited.

State childcare licensing agencies are playing a larger role in various initiatives designed to improve the quality of childcare, working through the infrastructure of the early care and education system. Several states' licensing agencies are part of quality initiatives called quality ratings and improvement systems, such as tiered quality strategies (e.g., tiered reimbursement systems for participating providers who achieve levels of quality beyond basic licensing requirements), public funding to facilitate accreditation, professional development systems, and program assessments and technical assistance.

Sick Children

When children are ill, they may be excluded from out-of-home arrangements, and settings under state licensure are required to exclude children with certain conditions. Guidelines for health and safety in out-of-home care from the American Academy of Pediatrics, the American Public Health Association, and the National Resource Center for Health and Safety in Child Care and Early Education offer recommendations regarding the conditions under which sick children should and should not be excluded from group programs (Table 17-1). State laws typically mirror these guidelines but may be stricter in some states.

Most families need to make arrangements to keep sick children at home (such as staying home from work or having backup plans with an alternative caregiver). Alternative care arrangements outside the home for sick children are relatively rare but may include either (1) care in the child's own center, if it offers special provisions designed for the care of ill children (sometimes called the infirmary model or sick daycare), or (2) care in a center that serves only children with illness or temporary conditions. Although it is important that such arrangements emphasize preventing further spread of disease, one study found no occurrence of additional transmission of communicable disease in children attending a sick center. The impact of group care of ill children on their subsequent health and on the health of their families and community is unknown.

CHILDCARE'S ROLE IN CHILD HEALTH AND DEVELOPMENT

Characteristics of Childcare and Associations with Child Developmental Outcomes

High-quality childcare is characterized by warm, responsive, and stimulating interactions between children and caregivers. In high-quality interactions, caregivers express positive feelings toward their children; are emotionally involved, engaged, and aware of the child's needs and sensitive and responsive to their initiations; speak directly with children in a manner that is elaborative and stimulating while being age-appropriate; and ask questions and encourage children's ideas and verbalizations. Structural quality features of the setting, including ratio of children to adults, group size, and caregiver education and training, act indirectly on child outcomes by facilitating high-quality child–caregiver interactions. It would be difficult for even the most sensitive and stimulating provider to engage in high-quality interactions with each child, if the provider was the sole caregiver of 10 toddlers.

The quality, quantity, type of setting, and stability of childcare experienced by young children contribute to child development. Childcare use by itself does not affect mother–child attachment. Only when combined with low maternal sensitivity and responsiveness does poor-quality childcare, larger quantities of childcare, or multiple childcare arrangements predict greater likelihood of insecure attachment.

Adjusting for family factors (i.e., parental income, education, race/ethnicity, family structure, parental sensitivity) the quality of childcare has a unique and consistent, albeit small, association with child outcomes across most domains of development. The type of childcare setting has unique effects, controlling for quality, with results from numerous studies demonstrating that center-based care is associated with better language and preacademic performance than home-based care. Quantity of care (hours per week) may also have unique effects, but findings are mixed, with some studies demonstrating small associations between greater quantity and elevated behavior problems, and other studies finding no associations for most children. Instability in childcare—over the course of a day, such as with rotating staff or multiple arrangements, or over time, with frequent changes in arrangements—does have negative effects on children's language and internalizing problems. Also, as childcare settings naturally have packages of quality characteristics, which are a mix of lower- and

Table 17-1 Conditions That Do and Do Not Require Exclusion from Group Childcare Settings

CONDITIONS THAT REQUIRE EXCLUSION	COMMENTS
If any of these 3 key criteria for exclusion of children who are ill are met, the child should be temporarily excluded, regardless of the type of illness:	
Illness preventing the child from participating comfortably in activities as determined by the childcare provider	Providers should specify in their policies, approved by the facilities' healthcare consultant, what severity level of illness the facility can manage, and how much and what types of illness will be addressed: • Severity level 1 consists of children whose health condition is accompanied by high interest and complete involvement in activity associated with an absence of symptoms of illness (such as children recovering from pinkeye, rash, or chickenpox), but who need further recuperation time • Severity level 2 encompasses children whose health condition is accompanied by a medium activity level because of symptoms (such as children with low-grade fever, children at the beginning of an illness, and children in the early recovery period of an illness) • Severity level 3 is composed of children whose health condition is accompanied by a low activity level because of symptoms that preclude much involvement
Illness resulting in a greater need for care than the childcare staff can provide without compromising the health and safety of the other children as determined by the childcare provider	
Illness that poses a risk of spread of harmful diseases to others	
In addition to the above key criteria, temporary exclusion is recommended when the child has any of the following conditions:	
Fever (temperature above 38°C [101°F] orally, above 38.9°C [102°F] rectally, or above 37.8°C [100°F] or higher taken axillary [armpit] or measured by an equivalent method) and behavior change or other signs and symptoms (e.g., sore throat, rash, vomiting, diarrhea)	Accompanied by behavior changes or other signs or symptoms of illness until medical professional evaluation finds the child able to be included at the facility
Acute change in behavior including lethargy/lack of responsiveness, inexplicable irritability or persistent crying, difficult breathing, or having a quickly spreading rash	Until evaluation by a medical professional finds the child able to be included at the facility
Diarrhea (defined by watery stools or decreased form of stool that is not associated with changes of diet). Exclusion is required for all diapered children whose stool is not contained in the diaper and toilet-trained children if the diarrhea is causing soiled pants or clothing	Readmission after diarrhea can occur when diapered children have their stool contained by the diaper (even if the stools remain loose) and when toilet-trained children are continent. Special circumstances that require specific exclusion criteria include the following: • Toxin-producing *Escherichia coli* or *Shigella* infection, until stools are formed and test results of 2 stool cultures obtained from stools produced 24-hr apart do not detect these organisms • *Salmonella* serotype Typhi infection, until diarrhea resolves and, in children younger than age 5 yr, 3 negative stool cultures obtained with 24-hr-intervals are obtained
Blood or mucus in stool	Not explained by dietary change, medication, or hard stools
Vomiting illness	More than 2 times in the previous 24 hr, unless the vomiting is determined to be caused by a noninfectious condition and the child remains adequately hydrated
Abdominal pain	Persistent (continues more than 2 hr) or intermittent associated with fever or other signs or symptoms
Mouth sores with drooling	Unless the child's primary care provider or local health department authority states that the child is noninfectious
Rash with fever or behavior changes	Until the primary care provider has determined that the illness is not an infectious disease
Active tuberculosis	Until the child's primary care provider or local health department states child is on appropriate treatment and can return
Impetigo	Until treatment has been started
Streptococcal pharyngitis (i.e., strep throat or other streptococcal infection)	Until 24 hr after treatment has been started
Purulent conjunctivitis	Defined as pink or red conjunctiva with white or yellow eye discharge, until after treatment has been initiated
Pediculosis (head lice)	Until after the first treatment *Note:* Exclusion is not necessary before the end of the program day
Scabies	Until after treatment has been given

Continued

Table 17-1 Conditions That Do and Do Not Require Exclusion from Group Childcare Settings—cont'd

CONDITIONS THAT REQUIRE EXCLUSION	COMMENTS
Varicella-zoster (chickenpox)	Until all lesions have dried or crusted (usually 6 days after onset of rash)
Rubella	Until 6 days after onset of rash
Pertussis	Until 5 days of appropriate antibiotic treatment
Mumps	Until 5 days after onset of parotid gland swelling
Measles	Until 4 days after onset of rash
Hepatitis A virus	Until 1 wk after onset of illness or jaundice if the child's symptoms are mild or as directed by the health department
Any child determined by the local health department to be contributing to the transmission of illness during an outbreak	
CONDITIONS THAT DO NOT REQUIRE EXCLUSION	**COMMENTS**
Common colds, runny noses	Regardless of color or consistency of nasal discharge
A cough not associated with an infectious disease or a fever	
Watery, yellow or white discharge or crusting eye discharge without fever, eye pain, or eyelid redness	
Presence of bacteria or viruses in urine or feces in the absence of illness symptoms, like diarrhea	Exceptions include children infected with highly contagious organisms capable of causing serious illness
Pink eye (bacterial conjunctivitis) indicated by pink or red eyelids after sleep	If 2 unrelated children in the same program have conjunctivitis, the organism causing the conjunctivitis may have a higher risk for transmission and a child healthcare professional should be consulted.
Fever without any signs or symptoms of illness in children who are older than 6 mo regardless of whether acetaminophen or ibuprofen was given	If the child is behaving normally but has a fever of below 38.9°C (102°F) rectally or the equivalent, the child should be monitored, but does not need to be excluded for fever alone
Rash without fever and without behavioral changes	
Lice or nits	Exclusion for treatment of an active lice infestation may be delayed until the end of the day
Ringworm	Exclusion for treatment may be delayed until the end of the day
Molluscum contagiosum	Do not require exclusion or covering of lesions
Thrush (i.e., white spots or patches in the mouth or on the cheeks or gums)	
Fifth disease	Once the rash has appeared
Methicillin-resistant *Staphylococcus aureus* (MRSA) without an infection or illness that would otherwise require exclusion	Known MRSA carriers or colonized individuals should not be excluded
Cytomegalovirus infection	
Chronic hepatitis B infection	
HIV infection	
Asymptomatic children who have been previously evaluated and found to be shedding potentially infectious organisms in the stool	Children who are continent of stool or who are diapered with formed stools that can be contained in the diaper may return to care
Children with chronic infections conditions that can be accommodated in the program according to the legal requirement of federal law in the Americans with Disabilities Act	The act requires that childcare programs make reasonable accommodations for children with disabilities and/or chronic illnesses, considering each child individually

Adapted from American Academy of Pediatrics, American Public Health Association, National Resource Center for Health and Safety in Child Care and Early Education: Stepping stones to caring for our children: national health and safety performance standards: guidelines for early care and education programs, third edition, *Elk Grove Village, IL, 2013, Authors, pp 46–52, available at: http://nrckids.org/index.cfm/products/stepping-stones-to-caring-for-our-children-3rd-edition-ss3/stepping-stones-to-caring-for-our-children-3rd-edition-ss3/*

higher-quality indicators, the bundle of features in a childcare arrangement may be another meaningful way for a parent to consider the potential effects of an arrangement on their child.

When a healthcare provider talks with a parent about the parent's child's childcare arrangement, it is also important to consider the individual child's characteristics, health concerns, dispositions, and even physiologic responses to the environment. Like all environments, childcare is experienced differently by different children. An average environment can often sufficiently compensate for the typical regulatory capacities of most children, but when an environment lacks adequate support for a child's unique needs, healthy development can be further compromised. Some children may be more vulnerable to bad childcare (or particularly responsive to good childcare), such as children with difficult or fearful temperaments, especially if their home environments are characterized by more risk factors, such as poverty or high conflict with a parent.

Several large studies have found that most U.S. childcare is of "poor to mediocre" quality. In one study, only 14% of centers (8% of

center-based infant care) were found to provide developmentally appropriate care, while 12% scored at minimal levels that compromised health and safety (40% for infant care). In another study, 58% of family daycare homes provided adequate or custodial care, and only 8% provided good care. Children with the greatest amount of family risk may be the most likely to receive childcare that is substandard in quality. Many children from lower-risk families also receive lower-quality care, and despite their advantages at home, these children may not be protected from the negative effects of poor-quality care.

Affordable, accessible, high-quality childcare is hard to find. Middle-class families spend approximately 6% of their annual income on childcare expenses, whereas poor families spend approximately 33% (on par with housing expenses). Infant and toddler care is particularly expensive with fewer available slots. For a married couple with children, the average cost of full-time center care for 1 infant ranges from 7% to approximately 19% of the state median income, depending on the state, and the average cost of center care for one 4 yr old exceeds 10% of the median household income in 21 states and the District of Columbia. For single parents, the average cost of center-based infant care exceeds 25% of median income in every state. The average cost of family childcare is only slightly lower.

In addition to the stress of meeting such a high expense, many parents worry that their child will feel unhappy in group settings, will suffer from separation from the parents, or will be subjected to neglect or abuse. This worry is especially likely among low-income parents with more risk factors, fewer resources, and fewer high-quality options available. Parents are the purchasers but not the recipients of care, and are not in the best position to judge its quality. Many parents are first-time purchasers of childcare with little experience and very immediate needs, selecting care in a market that does little to provide them with useful information about childcare arrangements. In many states, efforts are underway to improve quality and provide parents with quality information, but several states do not have a quality rating and information system, and programs in states that do are still emerging, and testing of effectiveness is still underway. To inform their care decisions, parents may turn to their child's pediatrician as the only professional with expertise in child development with whom they have regular and convenient contact.

Childcare and Child Health

A disproportionate number of sudden infant death syndrome (SIDS) deaths occur in childcare centers or family-based childcare homes (approximately 20%). Infants who are back-sleepers at home, but are put to sleep on their fronts in childcare settings, have a higher risk of SIDS. Providers and parents should be made aware of the importance of placing infants on their backs to sleep (see Chapter 375).

Children enrolled in childcare are also of an age that places them at increased risk for acquiring infectious diseases. Participation in group settings elevates exposure. Children enrolled in such settings have a higher incidence of illness (upper respiratory tract infections, otitis media, diarrhea, hepatitis A infections, skin conditions, and asthma) than those cared for at home, especially in the preschool years; these illnesses have no long-term adverse consequences. Childcare providers that follow childcare licensure guidelines for handwashing, diapering, and food handling, and that manage child illness appropriately, can reduce communicable illnesses.

There is debate about whether childcare exposure serves as a risk or protective factor for asthma. One cross-sectional study found that preschoolers in childcare had increased risk of the common cold and otitis media, and children who began childcare before the age of 2 yr had increased risk of developing recurrent otitis media and asthma. However, a longitudinal study found that children who were exposed to older children at home or to other children at childcare during the 1st 6 mo of life were less likely to have frequent wheezing from age 6-13 yr, suggesting that childcare exposure may protect against the development of asthma and frequent wheezing later in childhood. A 10 yr follow-up of a birth cohort found no association between childcare attendance and respiratory infections, asthma, allergic rhinitis, or skin prick test reactivity. Another study found that in the 1st yr of elementary school, children who had attended childcare had fewer absences from school, half as many episodes of asthma, and less acute respiratory illness than their peers who had never attended childcare. These results are perhaps related to protection against respiratory illness as a result of early exposure or a shift in the age-related peak of illness, though selection of illness-prone children into home care may play a role. Other factors may also be relevant to this issue, such as children in childcare potentially being less exposed to passive smoking than children at home.

Childcare and Children with Special Needs

The needs of children with mental, physical, or emotional disabilities who, because of their chronic illness, require special care and instruction may require particular attention when it comes to their participation in most childcare settings. Guiding principles of services for children with disabilities advocate supporting children in natural environments, including childcare. Furthermore, the Americans with Disabilities Act and Section 504 of the Rehabilitation Act of 1973 prohibit discrimination against children and adults with disabilities by requiring equal access to offered programs and services.

Although many childcare providers and settings are unprepared to identify or administer services for children with special needs, childcare could be utilized for delivery of support services to these children and/or for linking families to services, such as early intervention and doctor referrals. Furthermore, pediatricians can draw upon childcare providers to help provide important evaluative data regarding a child's well-being, as these providers have extensive daily contact with the child and may have broad, professional understanding of normative child development. A childcare provider may be the first to identify a child's potential language delay. Childcare providers are also necessary and valuable partners in the development and administration of early intervention service plans.

Children with special needs may be eligible for services under the Individuals with Disabilities Education Act (IDEA) (see Chapter 36). The purpose of this law is to provide "free appropriate public education," regardless of disability or chronic illness, to all eligible children, birth to 21 yr, in a natural and/or least-restrictive environment. Eligible children include those with mental, physical, or emotional disabilities who, because of their disability or chronic illness, require special instruction to learn. As a part of these services, a formal plan of intervention is to be developed by the service providers, families, and the children's healthcare providers. Federal funds are available to implement a collaborative early intervention system of services for eligible infants and toddlers between the ages of birth and 3 yr and their families. These services include screening, assessment, service coordination, and collaborative development of an **individualized family service plan (IFSP).** The IFSP describes early intervention services for the infant or toddler and family, including family support and the child's health, therapeutic, and educational needs. An understanding of the child's routines and real-life opportunities and activities, such as eating, playing, interacting with others, and working on developmental skills, is crucial to enhancing a child's ability to achieve the functional goals of the IFSP. Therefore it is critical that childcare providers be involved in IFSP development or revision, with parental consent. Childcare providers should also become familiar with the child's IFSP and understand the providers' role and the resources available to support the family and childcare provider.

Additionally, IDEA provides support for eligible preschool age children to receive services through the local school district. This includes development of a written **individualized education program (IEP)**, with implementation being the responsibility of the local education agency in either a public or private preschool setting. As with IFSPs, childcare providers should become familiar with the preschooler's special needs as identified in the IEP and may become involved, with parental consent, in IEP development and review meetings. In cases where children may have or be at risk of developmental delays, a diagnosis is important for obtaining and coordinating services and further evaluation. To this end, pediatricians can partner with childcare providers to screen and monitor children's behavior and development.

ROLE OF PEDIATRIC PROVIDERS IN CHILDCARE

Advising Parents on Childcare Selection

Organized professional guidance in choosing childcare is insufficient. Pediatricians can help parents understand the importance for their child's development of selecting high-quality care by describing how it looks and providing referrals and tips on how to find and select high-quality childcare (Table 17-2). In addition, pediatricians can help parents determine how to adjust childcare arrangements to best meet their child's specific needs (e.g., allergies, eating and sleeping habits, temperament and stress-regulation capacities). For most parents, finding childcare that they can afford, access, manage, and accept as a good environment for their child is a very difficult process and one many parents find distressing. Many parents are also worried about how their child will fare in childcare (e.g., Will their child feel distressed by group settings, suffer from separation from the parents, or even be subjected to neglect or abuse?). These worries are especially likely among low-income parents with fewer family and community resources to draw upon. A few parents may think of childcare only as babysitting, and may not consider the consequences for their child's cognitive, linguistic, and social development, focusing solely on whether the child is safe and warm. These parents may be less likely to select a high-quality childcare arrangement, which is especially problematic if the family is facing socioeconomic challenges that already place them at risk of receiving lower-quality care for their children. For these parents, it is vital to stress the importance of quality and its implications for their child's cognitive, language, and behavioral development and school readiness.

Advising Parents on Childcare Health Issues

Parents of infants should be advised to ensure that childcare providers put infants on their back to sleep to prevent SIDS. Also, pediatricians should emphasize the importance of following vaccination schedules; most states require compliance for children to participate in licensed group childcare settings.

When children are ill, parents should be advised to follow guidelines for inclusion and exclusion (see Table 17-1). Parents may disagree with childcare staff about whether a child meets or does not meet the exclusion criteria. However, professional guidelines state that "if … the reason for exclusion relates to the child's ability to participate or the caregiver's/teacher's ability to provide care for the other children, the caregiver/teacher should not be required to accept responsibility for the care of the child." (http://nrckids.org/index.cfm/products/stepping-stones-to-caring-for-our-children-3rd-edition-ss3/).

Helping Children with Special Needs

Pediatricians should work with parents and communicate with other service providers and early intervention staff to identify problems, remove access barriers, and coordinate service delivery for children with special needs. They should also encourage involvement of parents and childcare providers in IFSP or IEP plan development.

Consulting and Partnering with Childcare Providers

Most state regulations mandate that licensed programs have a formal relationship with a healthcare provider. Additional state efforts include mental health consultation models to support providers, who are often not well trained in managing child behavior, and build capacity to raise quality for all children. Early childhood mental health consultation links a mental health professional with an early education and care provider in an ongoing problem-solving and capacity-building relationship.

Pediatricians can provide consultation to childcare providers about measures to protect and maintain the health and safety of children and staff. This may include consultation regarding promoting practices to prevent SIDS; preventing and reducing the spread of communicable disease; reducing allergen, toxin, and parasite exposure; ensuring vaccinations for children and staff; removing environmental hazards; and preventing injuries.

Chapter 18

Loss, Separation, and Bereavement

Megan E. McCabe and Janet R. Serwint

All children will experience involuntary separations, whether from illness, death, or other causes, from loved ones at some time in their lives. Relatively brief separations of children from their parents, such as vacations, usually produce minor transient effects, but more enduring and frequent separation may cause sequelae. The potential impact of each event must be considered in light of the age and stage of development of the child, the particular relationship with the absent person, and the nature of the situation.

SEPARATION AND LOSS

Separations may be from temporary causes, such as vacations, parental job restrictions, natural disasters, or parental or sibling illness requiring hospitalization. More long-term separations occur as a result of divorce, placement in foster care, or adoption, whereas permanent separation may occur because of death. The initial reaction of young children to separation of any duration may involve crying, either of a tantrum-like, protesting type, or of a quieter, sadder type. Children's behavior may appear subdued, withdrawn, fussy, or moody, or they may demonstrate resistance to authority. Specific problems may include poor appetite, behavior issues such as acting against caregiver requests, reluctance to go to bed, sleep problems, or regressive behavior, such as requesting a bottle or bed-wetting. School-age children may experience impaired cognitive functioning and poor performance in school. Some children may repeatedly ask for the absent parent and question when the absent parent will return. The child may go to the window or door or out into the neighborhood to look for the absent parent; a few may even leave home or their place of temporary placement to search for their parents. Other children may not refer to the parental absence at all.

A child's response to reunion may surprise or alarm an unprepared parent. A parent who joyfully returns to the family may be met by wary or cautious children. After a brief interchange of affection, children may seem indifferent to the parent's return. This response may indicate anger at being left and wariness that the event will happen again, or the child may feel, as a result of magical thinking, as if the child caused the parent's departure. If the mother who frequently says "Stop it, or you'll give me a headache" is hospitalized, the child may feel at fault and guilty. As a result of these feelings, children may seem to be more closely attached to the other present parent than to the absent one, or even to the grandparent or babysitter who cared for them during their parent's absence. Some children, particularly younger ones, may become more clinging and dependent than they were before the separation, while continuing any regressive behavior that occurred during the separation. Such behavior may engage the returned parent more closely and help to reestablish the bond that the child felt was broken. Such reactions are usually transient and within 1-2 wk, children will have recovered their usual behavior and equilibrium. Recurrent separations may tend to make children more wary and guarded about reestablishing the relationship with the repeatedly absent parent, and these traits may affect other personal relationships. Parents should be advised not to try to ameliorate a child's behavior by threatening to leave.

DIVORCE

More sustained experiences of loss, such as divorce or placement in foster care, can give rise to the same kinds of reactions noted earlier, but they are more intense and possibly more lasting. Currently in the United States, approximately 40% of marriages end in divorce. Divorce has been found to be associated with negative parent functioning, such as parental depression and feelings of incompetence, negative child behavior, such as noncompliance and whining, and negative parent–child interaction, such as inconsistent discipline, decreased communication, and decreased affection. Greater childhood distress is associated with greater parental distress. Continued parental conflict and loss of contact with the noncustodial parent, usually the father, is common. Two of the most important factors that contribute to morbidity of the children in a divorce include parental psychopathology and disrupted parenting before the separation. The year following the divorce is the period when problems are most apparent; these problems tend to dissipate over the next 2 yr. Depression may be present 5 yr later, and educational or occupational decline may occur even 10 yr later. It is difficult to sort out all of the confounding factors. Children may suffer when exposed to parental conflict that continues after divorce, and in some cases may escalate. The degree of interparental conflict may be the most important factor associated with child morbidity. A continued relationship with the noncustodial parent, as long as there is minimal interparental conflict, was a factor associated with more positive outcomes.

School-age children may respond with evident depression, may seem indifferent, or may be markedly angry. Other children appear to deny or avoid the issue, behaviorally or verbally. Most children cling to the hope that the actual placement or separation is not real and are only temporary. The child may experience guilt by feeling that the loss, separation, or placement represents rejection and perhaps punishment for misbehavior. Children may protect a parent and assume guilt, believing that their own "badness" caused the parent to depart. Outwardly blaming parents may be perceived by a child as emotionally risky; parents who discover that a child harbors resentment might punish the child further for these thoughts or feelings. Children who feel that their misbehavior caused their parents to separate or become divorced have the fantasy that their own trivial or recurrent behavioral patterns caused their parents to become angry at each other. Some children have behavioral or psychosomatic symptoms and unwittingly adopt a "sick" role as a strategy for reuniting their parents.

In response to divorce of parents and the subsequent separation and loss, older children and adolescents commonly show intense anger. Five yr after the breakup, approximately ⅓ of children report intense unhappiness and dissatisfaction with their lives and their reconfigured families, another ⅓ show clear evidence of a satisfactory adjustment, whereas the remaining ⅓ demonstrate a mixed picture, with good achievement in some areas and faltering achievement in others. After 10 yr, approximately 45% do well, but 40% may have academic, social, and/or emotional problems. As adults, some are reluctant to form intimate relationships, fearful of repeating their parents' experience. Parental divorce has a moderate long-term negative impact on the adult mental health status of children who had experienced it, even after controlling for changes in economic status and problems before divorce. Good adjustment of children after a divorce is related to ongoing involvement with 2 psychologically healthy parents who minimize conflict, and to the siblings and other relatives who provide a positive support system. Divorcing parents should be encouraged to avoid adversarial processes and to use a trained mediator to resolve disputes if needed. Joint custody arrangements may reduce ongoing parental conflict, but children in joint custody may feel overburdened by the demands of maintaining a strong presence in 2 homes.

When the primary care provider is asked about the effects of divorce, parents should be informed that different children may have different reactions, but that the parents' behavior and the way they interact with each other will have a major and long-term effect on the child's adjustment. The continued presence of both parents in the child's life, with minimal interparental conflict, is most beneficial to the child.

MOVE/FAMILY RELOCATION

A significant proportion of the population of the United States changes residence each year. The effects of this movement on children and families are frequently overlooked. For children, the move is essentially involuntary and out of their control. When such changes in family

structure as divorce or death precipitate moves, children face the stresses created by both the precipitating events and the move itself. Parental sadness surrounding the move may transmit unhappiness to the children. Children who move lose their old friends, the comfort of a familiar bedroom and house, and their ties to school and community. They not only must sever old relationships but also are faced with developing new ones in new neighborhoods and new schools. Children may enter neighborhoods with different customs and values, and because academic standards and curricula vary among communities, children who have performed well in one school may find themselves struggling in a new one. Frequent moves during the school years are likely to have adverse consequences on social and academic performance.

Migrant children and children who emigrate from other countries present with special circumstances. These children not only need to adjust to a new house, school, and community but also need to adjust to a new culture and, in many cases, a new language. Because children have faster language acquisition than adults, they may function as translators for the adults in their families. This powerful position may lead to role reversal and potential conflict within the family. In the evaluation of migrant children and families, it is important to ask about the circumstances of the migration, including legal status, violence or threat of violence, conflict of loyalties, and moral, ethical, and religious differences.

Parents should prepare children well in advance of any move and allow them to express any unhappy feelings or misgivings. Parents should acknowledge their own mixed feelings and agree that they will miss their old home while looking forward to a new one. Visits to the new home in advance are often useful preludes to the actual move. Transient periods of regressive behavior may be noted in preschool children after moving, and these should be understood and accepted. Parents should assist the entry of their children into the new community, and whenever possible, exchanges of letters and visits with old friends should be encouraged.

SEPARATION BECAUSE OF HOSPITALIZATION

Potential challenges for hospitalized children include coping with separation, adapting to the new hospital environment, adjusting to multiple caregivers, seeing very sick children, and sometimes experiencing the disorientation of intensive care, anesthesia, and surgery. To help mitigate potential problems, a preadmission visit to the hospital is important to allow the child to meet the people who will be offering care and ask questions about what will happen. Parents of children younger than 5-6 yr of age should room with the child if feasible. Older children may also benefit from parents staying with them while in the hospital, depending on the severity of their illness. Creative and active recreational or socialization programs with child life specialists, chances to act out feared procedures in play with dolls or mannequins, and liberal visiting hours, including visits from siblings, are all helpful. Sensitive, sympathetic, and accepting attitudes toward children and parents by the hospital staff are very important. Healthcare providers need to remember that parents have the best interest of their children at heart and know their children the best. Whenever possible, school assignments and tutoring for the hospitalized children should be available in order to engage the child intellectually and prevent them from falling behind in their scholastic achievements.

The psychologic aspects of illness should be evaluated from the outset, and physicians should act as a model for parents and children by showing interest in a child's feelings, allowing them a venue for expression, and demonstrating that it is possible and appropriate to communicate discomfort in verbal, symbolic language. Continuity of medical personnel may be reassuring to the child and family.

MILITARY FAMILIES

More than 2 million children live in military families in the United States, and approximately 50% of them obtain medical care in the community rather than at a military medical facility.

Children whose parents are serving in the military may experience loss and separation in multiple ways. These include frequent relocations, relocation to foreign countries, and duty-related separation from parents. In recent years, the most impactful experiences have been repeated wartime deployments of parents and of the deaths of parents during military service.

All branches of the military have increased their focus on preparing and supporting military families for a service member's deployment to improve family coping. Military families composed of young parents and young children are at risk for child maltreatment in the context of repeated or prolonged deployments.

PARENTAL/SIBLING DEATH

Approximately 5-8% of U.S. children will experience parental death; rates are much higher in other parts of the world that are more directly affected by war, AIDS, and natural disasters. Anticipated deaths from chronic illness may place a significant strain on a family, with frequent bouts of illness, hospitalization, disruption of normal home life, absence of the ill parent, and perhaps more responsibilities placed on the child. Additional strains include changes in daily routines, financial pressures, and the need to cope with aggressive treatment options.

Children can and should continue to be involved with the sick parent or sibling, but they need to be prepared for what they will see in the home or hospital setting. The stresses that a child will face include visualizing the physical deterioration of the family member, helplessness, and emotional lability. Forewarning the child that the family member may demonstrate physical changes, such as appearing thinner or losing hair will help the child to adjust. These warnings, combined with simple yet specific explanations of the need for equipment, such as a nasogastric tube for nutrition, an oxygen mask, or a ventilator, will help lessen the child's fear. Children should be honestly informed of what is happening, in language they can understand, allowing them choices, but with parental involvement in decision making. They should be encouraged, but not forced, to see their ill family member. Parents who are caring for a dying spouse or child may be too emotionally depleted to be able to tend to their healthy child's needs or to continue regular routines. Children of a dying parent may suffer the loss of security and belief in the world as a safe place, and the surviving parent may be inclined to impose his or her own need for support and comfort onto the child. However, the well parent and caring relatives must keep in mind that children need to be allowed to remain children, with appropriate support and attention. Sudden, unexpected deaths lead to more anxiety and fear, because there was no time for preparation and uncertainty as to explanations.

GRIEF AND BEREAVEMENT

Grief is a personal, emotional state of bereavement or an anticipated response to loss, such as a death. Common reactions include sadness, anger, guilt, fear, and at times, relief. The normality of these reactions needs to be emphasized. Most bereaved families remain socially connected and expect that life will return to some new, albeit different, sense of normalcy. The pain and suffering imposed by grief should never be automatically deemed "normal" and thus neglected or ignored. In uncomplicated grief reactions, the steadfast concern of the pediatrician can help promote the family's sense of well-being. In more distressing reactions (such as those seen in traumatic grief of sudden deaths), the pediatrician may be a major, first-line force in helping children and families address their loss.

Participation in the care of a child with a life-threatening or terminal illness is a profound experience. Parents experience much anxiety and worry during the final stages of their child's life. In 1 study at a children's hospital, 45% of children dying from cancer died in the pediatric intensive care unit, and parents report that 89% of their children suffered "a lot" or "a great deal" during the last month of life. Physicians consistently underreport children's symptoms in comparison to parents' reports. Better ways are needed to provide for dying children, and to maintain honest and open communication, provide appropriate pain management, and meet the families' wishes as to the preferred location of the child's death, in some cases in their own home. Inclusion of multiple disciplines, such as hospice, clergy, nursing, pain service, child life specialists, and social work, often helps to fully support families during this difficult experience.

The practice of withholding information from children and parents regarding a child's diagnosis and prognosis has generally been abandoned because physicians have learned that protecting parents and patients from the seriousness of their child's condition does not alleviate concerns and anxieties. Even very young children may have a real understanding of their illness. Children who have serious diseases and are undergoing aggressive treatment and medication regimens, but are told by their parents that they are okay, are not reassured by their parents. These children understand that something serious is happening to them, and they are often forced to suffer in silence and isolation because the message they have been given by their parents is to not discuss it and to maintain a cheerful demeanor. Children have the right to know their diagnosis and should be informed early in their treatment. The content and depth of the discussion needs to be tailored to the child's personality and developmental level of understanding. Parents have choices as to how to orchestrate the disclosure. Parents may want to be the ones to inform the child themselves, may choose for the pediatric healthcare provider to do so, or may do it in partnership with the pediatrician.

A death, especially the death of a family member, is the most difficult loss for a child. Many changes in normal patterns of functioning may occur, including loss of love and support from the deceased family member, a change in income, the possible need to relocate, less emotional support from surviving family members, altering of routines, and a possible change in status from sibling to only child. Relationships between family members may become strained, and children may blame themselves or other family members for the death of a parent or sibling. Bereaved children may exhibit many of the emotions discussed earlier as a result of the loss, in addition to behaviors of withdrawal into their own world, sleep disturbances, nightmares, and symptoms such as headache, abdominal pains, or possibly similar to those of the family member who has died. Children 3-5 yr of age who have experienced a family bereavement may show regressive behaviors such as bed-wetting and thumb sucking. School-age children may exhibit nonspecific symptoms, such as headache, abdominal pain, chest pain, fatigue, and lack of energy. Children and adolescents may also demonstrate enhanced anxiety should these symptoms resemble those of the family member who died. The presence of secure and stable adults who can meet the child's needs and who permit discussion about the loss is most important in helping a child to grieve. The pediatrician should help the family understand this necessary presence and encourage the protective functioning of the family unit. More frequent visits to the healthcare professional may be necessary to address these symptoms and provide reassurance when appropriate.

Death, separation, and loss as a result of natural catastrophes and human-made disasters have become increasingly common events in children's lives. Exposure to such disasters occurs either directly or indirectly, where the event is experienced through the media. Examples of indirect exposure include televised scenes of earthquakes, hurricanes, tsunamis, tornadoes and the terrorist attacks at the Boston Marathon in 2013 and in New York on September 11, 2001, with the subsequent news stories about anthrax and heightened states of alert. Children who experience personal loss in disasters tend to watch more television coverage than children who do not. Children without a personal loss watch as a way of participating in the event and may thus experience repetitive exposure to traumatic scenes and stories. The loss and devastation for a child who personally lives through a disaster is significant; the effect of the simultaneous occurrence of disaster and personal loss complicates the bereavement process as grief reactions become interwoven with posttraumatic stress symptoms (see Chapter 25). After a death that occurs as a result of aggressive or traumatic circumstances, access to expert help may be required. Under conditions of threat and fear, children seek proximity to safe, stable, protective figures.

It is important for parents to grieve with their children. Some parents want to protect their children from their grief, so they put on an outwardly brave front or do not talk about the deceased family member. Instead of the desired protective effect, the child receives the message that demonstrating grief or talking about death is wrong, leading the child to feel isolated, to grieve privately, or to delay grieving. The child may also conclude that the parents didn't really care about the deceased because they have forgotten the deceased so easily or demonstrate no emotion. The parents' efforts to avoid talking about the death may cause the parents to isolate themselves from their children at a time when the children most need them. Children need to know that their parents love them and will continue to protect them. Children need opportunities to talk about their relative's death and associated memories. A surviving sibling may feel guilty simply because he or she survived, especially if the death was the result of an accident that involved both children. Siblings' grief, especially when compounded by feelings of guilt, may be manifested by regressive behavior or anger. Parents should be informed of this possibility and encouraged to discuss the possibility with their children.

DEVELOPMENTAL PERSPECTIVE

Children's responses to death reflect the family's current culture, their past heritage, experiences, and the sociopolitical environment. Personal experience with terminal illness and dying may also facilitate children's comprehension of death and familiarity with mourning. Developmental differences in children's efforts to make sense of and master the concept and reality of death do exist and profoundly influence their grief reactions.

Children **younger than 3 yr** of age have little or no understanding of the concept of death. Despair, separation anxiety, and detachment may occur at the withdrawal of nurturing caretakers. Young children may respond in reaction to observing distress in others, such as a parent or sibling who is crying, withdrawn, or angry. Young children also express signs and symptoms of grief in their emotional states, such as irritability or lethargy, and in severe cases, mutism. If the reaction is severe, failure to thrive may occur.

Preschool children are in the preoperational cognitive stage, in which communication takes place through play and fantasy (see Chapter 6). They do not show well-established cause-and-effect reasoning. They feel that death is reversible, analogous to someone going away. In attempts to master the finality and permanence of death, preschoolers frequently ask unrelenting, repeated questions about when the person who died will be returning. This makes it difficult for parents, who may become frustrated because they don't understand why the child keeps asking and do not like the constant reminders of the person's death. The primary care provider has a very important role in helping families understand the child's struggle to comprehend death. Preschool children typically express magical explanations of death events, sometimes resulting in guilt and self-blame ("He died because I wouldn't play with him." "She died because I was mad at her."). Some children have these thoughts, but do not express them verbally because of embarrassment or guilt. Parents and primary care providers need to be aware of magical thinking and must reassure preschool children that their thoughts had nothing to do with the outcome. Children of this age are often frightened by prolonged, powerful expressions of grief by others. Children conceptualize events in the context of their own experiential reality, and therefore consider death in terms of sleep, separation, and injury. Young children express grief intermittently and show marked affective shifts over brief periods. Regression, accompanied by longing, sadness, and anger, may accompany grief.

Younger school-age children think concretely, recognize that death is irreversible, but believe it will not happen to them or affect them, and begin to understand biologic processes of the human body ("You'll die if your body stops working"). Information gathered from the media, peers, and parents forms lasting impressions. Consequently, they may ask candid questions about death that adults will have difficulty addressing ("He must have been blown to pieces, huh?").

Children 9 yr of age and older do understand that death is irreversible and that it may involve them or their families. These children tend to experience more anxiety, overt symptoms of depression, and somatic complaints than do younger children. School-aged children are often left with anger focused on the loved one, those who could not save the deceased, or those presumed responsible for the death. Contact with

the pediatrician may provide great reassurance, especially for the child with somatic symptoms, and particularly when the death followed a medical illness. School and learning problems may also occur, and these reactions are often linked to difficulty concentrating or preoccupation with the death. Close collaboration with the child's school may provide important diagnostic information and offer opportunities to mobilize intervention or support.

At 12-14 yr of age, children begin to use symbolic thinking, reason abstractly, and analyze hypothetical, or "what if," scenarios systematically. Death and the end of life become concepts, rather than events. Teenagers are often ambivalent about dependence and independence and may withdraw emotionally from surviving family members, only to mourn in isolation. Adolescents begin to understand complex physiologic systems in relationship to death. Since they are often egocentric, they may be more concerned about the impact of the death on themselves than about the deceased or other family members. Fascination with dramatic, sensational, or romantic death sometimes occurs and may find expression in copycat behavior, such as cluster suicides, as well as competitive behavior to forge emotional links to the deceased person ("He was my best friend."). Somatic expression of grief may revolve around highly complex syndromes (eating disorders or conversion reactions) as well as symptoms limited to the more immediate perceptions, as with younger children (stomachaches). Quality of life takes on meaning, and the teenager develops a focus on the future. Depression, resentment, mood swings, rage, and risk-taking behaviors can emerge as the adolescent seeks answers to questions of values, safety, evil, and fairness. Alternately, the adolescent may seek philosophical or spiritual explanations ("being at peace") to ease their sense of loss. The death of a peer may be especially traumatic.

Families often struggle with how to inform their children of the death of a family member. The answer depends on the child's developmental level. It is best to avoid misleading euphemisms and metaphor. A child who is told that the relative who died "went to sleep" may become frightened of falling asleep, resulting in sleep problems or nightmares. Children can be told that the person is "no longer living" or "no longer moving or feeling." Using examples of pets that have died sometimes can help children gain a more realistic idea of the meaning of death. Parents who have religious beliefs may comfort their children with explanations, such as "Your sister's soul is in heaven" or "Grandfather is now with God," provided those beliefs are honestly held. If these are not religious beliefs that the parents share, children will sense the insincerity and experience anxiety rather than the hoped-for reassurance. Children's books about death can provide an important source of information, and when read together, these books may help the parent to find the right words, while addressing the child's needs.

ROLE OF THE PEDIATRICIAN IN GRIEF

The pediatrician has an important role in assisting grieving families, because the death of a child has become an uncommon experience in our society. The pediatric healthcare provider who has had a longitudinal relationship with the family will be an important source of support in the disclosure of bad news and critical decision making, during both the dying process and the bereavement period.

The involvement of the healthcare provider may include being present at the time the diagnosis is disclosed, at the hospital or home at the time of death, being available to the family by phone during the bereavement period, sending a sympathy card, attending the funeral, and/or scheduling a follow-up visit. Attendance at the funeral sends a strong message that the family and their child are important, respected by the healthcare provider, and can also help the pediatric healthcare provider to grieve and reach personal closure about the death. A family meeting 1-3 mo later may be helpful because parents may not be able to formulate their questions at the time of death. This meeting allows the family time to ask questions, share concerns, and review autopsy findings (if one was performed), and allows the healthcare provider to determine how the parents and family are adjusting to the death.

Instead of leaving the family feeling abandoned by a healthcare system that they have counted on, this visit allows them to have continued support. This is even more important when the healthcare provider will be continuing to provide care for surviving siblings. The visit can be used to determine how the mourning process is progressing, detect evidence of marital discord, and evaluate how well surviving siblings are coping. This is also an opportunity to evaluate whether referrals to support groups or mental health providers may be of benefit. Continuing to recognize the child who has died is important. Families appreciate the receipt of a card on their child's birthday or the anniversary of their child's death.

The healthcare provider needs to be an educator about disease, death, and grief. The pediatrician can offer a safe environment for the family to talk about painful emotions, express fears, and share memories. By giving families permission to talk and modeling how to address children's concerns, the pediatrician demystifies death. Parents often request practical help. The healthcare provider can offer families resources, such as literature (both fiction and nonfiction), referrals to therapeutic services, and tools to help them learn about illness, loss, and grief. In this way, the physician reinforces the sense that other people understand what they are going through and helps to normalize their distressing emotions. The pediatrician can also facilitate and demystify the grief process by sharing basic tenets of grief therapy. There is no single right or wrong way to grieve. Everyone grieves differently; mothers may grieve differently than fathers, and children mourn differently than adults. Helping family members to respect these differences and reach out to support each other is critical. Grief is not something to "get over," but a lifelong process of adapting, readjusting, and reconnecting.

Parents may need help in knowing what constitutes normal grieving. Hearing, seeing, or feeling their child's presence may be a normal response. Vivid memories or dreams may occur. The pediatrician can help parents to learn that, although their pain and sadness may seem intolerable, other parents have survived similar experiences, and their pain will lessen over time.

Pediatricians are often asked whether children should attend the funeral of a parent or sibling. These rituals allow the family to begin their mourning process. Children older than 4 yr of age should be given a choice. If the child chooses to attend, the child should have a designated, trusted adult, who is not part of the immediate family, stay with the child, offer comfort, and be willing to leave with the child if the experience proves to be overwhelming. If the child chooses not to attend, the child should be offered additional opportunities to share in a ritual, go to the cemetery to view the grave, tell stories about the deceased, or obtain a keepsake object from the deceased family member as a remembrance.

In the era of regionalized tertiary care medicine, the primary care provider and medical home staff may not be informed when one of their patients dies in the hospital. Yet, this communication is critically important. Families assume their pediatrician has been notified, and often feel hurt when they don't receive some symbol of condolence. Because of their longitudinal relationship with the family, primary care providers may offer much needed support. There are practical issues, such as the need to cancel previously made appointments and the need to alert office and nursing staff so that they are prepared should the family return for a follow-up visit or for ongoing health maintenance care with the surviving siblings. Even minor illnesses in the surviving siblings may frighten children. Parents may contribute to this anxiety because their inability to protect the child who has died may leave them with a sense of guilt or helplessness. They may seek medical attention sooner or may be hypervigilant in the care of the siblings because of guilt over the other child's death, concern about their judgment, or the need for continued reassurance. A visit to the pediatrician can do a lot to allay their fears.

Clinicians must remain vigilant for risk factors in each family member and in the family unit as a whole. Primary care providers, who care for families over time, know bereft patients' premorbid functioning and can identify those at current or future risk for physical and psychiatric morbidity. Providers must focus on symptoms that interfere with a patient's normal activities and compromise a child's attainment of developmental tasks. Symptom duration, intensity, and severity, in context with the family's culture, can help identify

complicated grief reactions in need of therapeutic attention. Descriptive words, such as "unrelenting," "intense," "intrusive," or "prolonged," should raise concern. Total absence of signs of mourning, specifically, an inability to discuss the loss or express sadness, also suggests potential problems.

No specific sign, symptom, or cluster of behaviors identifies the child or family in need of help. Further assessment is indicated if the following occur: (1) persistent somatic or psychosomatic complaints of undetermined origin (headache, stomachache, eating and sleeping disorders, conversion symptoms, symptoms related to the deceased's condition, hypochondriasis); (2) unusual circumstances of death or loss (sudden, violent, or traumatic death; inexplicable, unbelievable, or particularly senseless death; prolonged, complicated illness; unexpected separation); (3) school or work difficulties (declining grades or school performance, social withdrawal, aggression); (4) changes in home or family functioning (multiple family stresses, lack of social support, unavailable or ineffective functioning of caretakers, multiple disruptions in routines, lack of safety); (5) concerning psychologic factors (persistent guilt or blame, desire to die or talk of suicide, severe separation distress, disturbing hallucinations, self-abuse, risk-taking behaviors, symptoms of trauma such as hyperarousal or severe flashbacks, grief from previous or multiple deaths). Children who are intellectually impaired may require additional support.

TREATMENT

Suggesting interventions outside the natural support network of family and friends can often prove useful to grieving families. Bereavement counseling should be readily offered if needed or requested by the family. Interventions that enhance or promote attachments and security, as well as give the family a means of expressing and understanding death, help to reduce the likelihood of future or prolonged disturbance, especially in children. Collaboration between pediatric and mental health professionals can help determine the timing and appropriateness of services.

Interventions for children and families who are struggling to cope with a loss in the community include gestures such as sending a card or offering food to the relatives of the deceased and teaching children the etiquette of behaviors and rituals around bereavement and mutual support. Performing community service or joining charitable organizations, such as fund-raising in memory of the deceased, may be useful. In the wake of a disaster, parents and older siblings can give blood or volunteer in search and recovery efforts. When a loss does not involve an actual death (e.g., parental divorce or geographic relocation), empowering the child to join or start a "divorced kids' club" in school or planning a "new kids in town" party may help. Participating in a constructive activity helps move the family away from a sense of helplessness and hopelessness and helps them to find meaning in their loss.

Psychotherapeutic services may benefit the entire family or individual members. Many support or self-help groups focus on specific types of losses (sudden infant death syndrome, suicide, widow/widowers, or AIDS) and provide an opportunity to talk with other people who have experienced similar losses. Family, couple, sibling or individual counseling may be useful, depending on the nature of the residual coping issues. Combinations of approaches may work well for children or parents with evolving needs. A child may participate in family therapy to deal with the loss of a sibling and use individual treatment to address issues of personal ambivalence and guilt related to the death.

The question of pharmacologic intervention for grief reactions often arises. Explaining that medication does not cure grief and often does not reduce the intensity of some symptoms (separation distress) can help. Although medication can blunt reactions, the psychologic work of grieving still must occur. The pediatrician must consider the patient's premorbid psychiatric vulnerability, current level of functioning, other available supports, and the use of additional therapeutic interventions. Medication, as a first line of defense, rarely proves useful in normal or uncomplicated grief reactions. In certain situations (severe sleep disruption, incapacitating anxiety, or intense hyperarousal), use of an anxiolytic or antidepressant medication for symptom relief and to provide the patient with the emotional energy to mourn may help. Medication used in conjunction with some form of psychotherapy, and in consultation with a psychopharmacologist, has optimal results.

Children who are refugees and may have experienced war, violence, or personal torture, while often resilient, may experience post-traumatic stress disorder if exposures were severe or repeated. Sequelae such as depression, anxiety, and grief need to be addressed, and mental health therapy is indicated. Cognitive behavioral treatment, use of journaling and narratives to bear witness to the experiences, and use of translators may be essential.

SPIRITUAL ISSUES

Responding to patients' and families' spiritual beliefs can help in comforting them during family tragedies. Offering to call members of pastoral care teams or their own spiritual leader can be a real support to them and aid in decision-making. Families have found it important to have their beliefs and their need for hope acknowledged in end-of-life care. The majority of patients report welcoming discussions on spirituality, which may help individual patients cope with illness, disease, dying, and death. In addressing spirituality, physicians need to follow certain guidelines, including maintaining respect for the patient's beliefs, following the patient's lead in exploring how spirituality affects the patient's decision making, acknowledging the limits of their own expertise and role in spirituality, and maintaining their own integrity by not saying or doing anything that violates their own spiritual or religious views. Healthcare providers should not impose their own religious or antireligious beliefs on patients, but rather should listen respectfully to their patients. By responding to spiritual needs, physicians may better aid their patients and families in end-of-life care and bereavement and take on the role of healers.

Chapter 19

Sleep Medicine

Judith A. Owens

Sleep regulation is also referred to as the *2-process* sleep system because it requires the simultaneous operation of 2 basic, highly coupled processes that govern sleep and wakefulness. The **homeostatic process** ("Process S"), regulates the length and depth of sleep, and may be related to the accumulation of adenosine and other sleep-promoting chemicals ("somnogens"), such as cytokines, during prolonged periods of wakefulness. This sleep pressure appears to build more quickly in infants and young children, thus limiting the duration that wakefulness can be sustained during the day and necessitating periods of daytime sleep (i.e., naps). The endogenous **circadian rhythms** ("Process C"), influence the internal organization of sleep and timing and duration of daily sleep–wake cycles, and govern predictable patterns of alertness throughout the 24 hr day. The "master circadian clock" that controls sleep–wake patterns, of which melatonin secretion is the principal biomarker, is located in the suprachiasmatic nucleus in the ventral hypothalamus. The "circadian clocks" govern the timing of multiple other physiologic systems in the body (e.g., cardiovascular reactivity, hormone levels, renal and pulmonary functions). Because the human circadian clock is actually slightly longer than 24 hr, intrinsic circadian rhythms must be synchronized or "entrained" to the 24 hr day cycle by environmental cues called **zeitgebers**. The **dark–light cycle** is the most powerful of the zeitgebers; light signals are transmitted to the suprachiasmatic nucleus via the circadian photoreceptor system within the retina (functionally and anatomically separate from the visual system), which switch the body's production of the hormone melatonin off

(light) or on (dark) by the pineal gland. Circadian rhythms are also synchronized by other external time cues, such as timing of meals and alarm clocks.

Sleep propensity (the relative level of sleepiness) or alertness experienced at any given time during a 24 hr period is partially determined by the homeostatic *sleep drive*, which, in turn, depends upon the duration and quality of previous sleep and the amount of time awake since the last sleep period. Interacting with this *sleep homeostat* is the 24 hr cyclic pattern or rhythm characterized by clock-dependent periods of maximum sleepiness (*circadian troughs*) and maximum alertness (*circadian nadirs*). There are 2 periods of maximum sleepiness, 1 in the late afternoon (3:00-5:00 PM) and 1 toward the end of the night (3:00-5:00 AM), and 2 periods of maximum alertness, 1 in mid-morning and 1 in the evening, just prior to sleep onset (the so-called forbidden zone or second-wind phenomenon).

There are significant consequences of the failure to meet basic sleep needs, termed insufficient/inadequate sleep or **sleep loss**. Sufficient sleep is a biologic imperative, necessary for optimal functioning and apparently for life. **Slow-wave sleep** (SWS) (i.e., N3, delta, or deep sleep) appears to be the most restorative form of sleep; it is entered into relatively quickly after sleep onset, it is preserved in the face of reduced total sleep time, and it increases (rebounds) after a night of restricted sleep. **Rapid eye movement** (REM) sleep (Stage R or "dream" sleep) appears to be involved in (1) completing vital cognitive functions, such as the consolidation of memory; (2) promoting the plasticity of the central nervous system (CNS); and (3) protecting the brain from injury. Sufficient amounts of both of these sleep stages are necessary for optimal cognitive functioning. Partial sleep loss (sleep restriction) on a chronic basis accumulates in what is termed a **sleep debt** and produces deficits equivalent to those seen under conditions of total sleep deprivation. If the sleep debt becomes large enough and is not voluntarily repaid by obtaining sufficient recovery sleep, the body may respond by overriding voluntary control of wakefulness. This results in periods of decreased alertness, dozing off, and unplanned napping, recognized as excessive daytime sleepiness. The sleep-restricted individual may also experience very brief (several seconds) repeated daytime microsleeps of which the individual may be completely unaware, but which, nonetheless, may result in significant lapses in attention and vigilance. There is also a relationship between the amount of sleep restriction and performance on cognitive tasks, particularly those requiring sustained attention and higher level cognitive skills (*executive functions*), with a decay in performance correlating with declines in sleep amounts.

Both insufficient quantity and poor quality of sleep in children and adolescents usually result in excessive daytime sleepiness and decreased daytime alertness levels. Sleepiness in children may be recognizable as drowsiness, yawning, and other classic "sleepy behaviors," but can also be manifested as mood disturbance, including complaints of moodiness, irritability, emotional lability, depression, and anger; fatigue and daytime lethargy, including increased somatic complaints (headaches, muscle aches); cognitive impairment, including problems with memory, attention, concentration, decision making, and problem solving; daytime behavior problems, including hyperactivity, impulsivity, and noncompliance; and academic problems, including chronic tardiness related to insufficient sleep and school failure resulting from chronic daytime sleepiness.

To evaluate sleep problems, it is important to have an understanding of what constitutes "normal" sleep in children and adolescents. Sleep disturbances, as well as many characteristics of sleep itself, have some distinctly different features in children from sleep and sleep disorders in adults. Changes in sleep architecture and the evolution of sleep patterns and behaviors reflect the physiologic/chronobiologic, developmental, and social/environmental changes that are occurring across childhood. These trends may be summarized as the gradual assumption of more adult sleep patterns as children mature:

1. Sleep is *the* primary activity of the brain during early development; for example, by age 2 yr, the average child has spent 9500 hr (~13 months) asleep compared to 8000 hr awake, and between 2 and 5 yr, the time asleep is equal to the time awake.
2. There is a gradual decline in the average 24 hr sleep duration from infancy through adolescence, which involves a decrease in both diurnal and nocturnal sleep amounts. The decline in daytime sleep (scheduled napping) results in termination of naps typically by around 5 yr of age. There is also a gradual continued decrease in nocturnal sleep amounts into late adolescence; however, the typical adolescent still requires 9-9.25 hr of sleep per night.
3. There is also a decline in the relative percentage of REM sleep from birth (50% of sleep) through early childhood into adulthood (25-30%), and a similar initial predominance of SWS that peaks in early childhood, drops off abruptly after puberty (40-60% decline), and then further decreases over the life span. This SWS preponderance in early life has clinical significance; for example, the high prevalence of partial arousal parasomnias (sleepwalking and sleep terrors) in preschool and early school-age children is related to the relative increased percentage of SWS in this age group.
4. The within-sleep ultradian cycle lengthens from about 50 minutes in the term infant to 90-110 minutes in the school-age child. This, again, has clinical significance in that there is typically a brief arousal or awakening during the night at the termination of each ultradian cycle. As the length of the cycles increase, there is a concomitant decrease in the number of these end-of-cycle arousals ("night wakings").
5. A gradual shift in the circadian sleep–wake rhythm to a delayed (later) sleep onset and offset time, linked to pubertal stage rather than chronological age, begins in middle childhood and accelerates in early to mid-adolescence. This biologic phenomenon often coincides with environmental factors, which further delay bedtime and advance wake time and result in insufficient sleep duration, including exposure to electronic "screens" (i.e., television and computer) in the evening, social networking, academic and extracurricular demands, and early (before 8 AM) high school start times.
6. Increasing irregularity of sleep–wake patterns is typically observed across childhood into adolescence; this is characterized by increasingly larger discrepancies between school night and non–school night bedtimes and wake times, and increased "weekend oversleep" in an attempt to compensate for chronic weekday sleep insufficiency. This practice not only fails to adequately address performance deficits associated with insufficient sleep on school nights, but further exacerbates the normal adolescent phase delay and results in additional circadian disruption (analogous to that experienced by shift workers).

Table 19-1 lists normal developmental changes in children's sleep.

COMMON SLEEP DISORDERS

Childhood sleep problems may be conceptualized as resulting from either inadequate duration of sleep for age and sleep needs (insufficient sleep quantity) or disruption and fragmentation of sleep (poor sleep quality) as a result of frequent, repetitive, and brief arousals during sleep. Less common but important causes of sleep disturbance in childhood involve inappropriate timing of the sleep period (as occurs in circadian rhythm disturbances), or primary disorders of excessive daytime sleepiness (central hypersomnias such as narcolepsy). Insufficient sleep is usually the result of difficulty initiating (delayed sleep onset) and/or maintaining sleep (prolonged night wakings), but, especially in older children and adolescents, may also represent a conscious lifestyle decision to sacrifice sleep in favor of competing priorities, such as homework and social activities. The underlying causes of sleep onset delay/prolonged night wakings or sleep fragmentation may, in turn, be related to primarily behavioral factors (e.g., bedtime resistance resulting in shortened sleep duration) and/or medical causes (e.g., obstructive sleep apnea causing frequent, brief arousals).

Certain pediatric populations are relatively more vulnerable to acute or chronic sleep problems. These include children with medical problems, including chronic illnesses or pain conditions, such as cystic fibrosis, asthma, and rheumatoid arthritis, and acute illnesses, such as otitis media; children taking medications or ingesting substances with

Table 19-1 Normal Developmental Changes in Children's Sleep

AGE CATEGORY	SLEEP DURATION AND SLEEP PATTERNS	ADDITIONAL SLEEP ISSUES	SLEEP DISORDERS
Newborn (0-2 mo)	Total sleep: 10-19 hr per 24 hr (average = 13-14.5 hr), may be higher in premature babies Bottlefed babies generally sleep for longer periods (2-5 hr bouts) than breastfed babies (1-3 hr) Sleep periods are separated by 1-2 hr awake No established nocturnal–diurnal pattern in the 1st few wk; sleep is evenly distributed throughout the day and night, averaging 8.5 hr at night and 5.75 hr during the day	The American Academy of Pediatrics issued a formal recommendation in 2005 advocating against bed sharing in the 1st yr of life, instead encouraging proximate but separate sleeping surfaces for mother and infant. Safe sleep practices for infants: • Place the baby on his or her back to sleep at night and during nap times • Place the baby on a firm mattress with a well-fitting sheet in a safety-approved crib • Do not use pillows or comforters • Cribs should not have corner posts over 1/16 in high or decorative cutouts • Make sure the baby's face and head stay uncovered and clear of blankets and other coverings during sleep	Most sleep issues that are perceived as problematic at this stage represent a discrepancy between parental expectations and developmentally appropriate sleep behaviors Newborns who are noted by parents to be extremely fussy and persistently difficult to console are more likely to have underlying medical issues, such as colic, gastroesophageal reflux, and formula intolerance
Infant (2-12 mo)	Total sleep: average is 12-13 hr (note that there is great individual variability in sleep times during infancy) Nighttime: average is 9-10 hr Naps: average is 3-4 hr	Sleep regulation or self-soothing involves the infant's ability to negotiate the sleep–wake transition, both at sleep onset and following normal awakenings throughout the night. The capacity to self-soothe begins to develop in the 1st 12 wk of life, and is a reflection of both neurodevelopmental maturation and learning Sleep consolidation, or "sleeping through the night," is usually defined by parents as a continuous sleep episode without the need for parental intervention (e.g., feeding, soothing) from the child's bedtime through the early morning. Infants develop the ability to consolidate sleep between 6 wk and 3 mo	Behavioral insomnia of childhood; sleep onset association type Sleep-related rhythmic movements (head banging, body rocking)
Toddler (1-3 yr)	Total sleep: average is 11-13 hr Nighttime: average is 9.5-10.5 hr Naps: average is 2-3 hr; decrease from 2 naps to 1 at average age of 18 mo	Cognitive, motor, social, language developmental issues impact on sleep Nighttime fears develop; transitional objects, bedtime routines important	Behavioral insomnia of childhood, sleep onset association type Behavioral insomnia of childhood, limit setting type
Preschool (3-5 yr)	Nighttime: average is 9-10 hr Naps decrease from 1 nap to no nap Overall, 26% of 4 yr olds and just 15% of 5 yr olds nap	Persistent cosleeping tends to be highly associated with sleep problems in this age group Sleep problems may become chronic	Behavioral insomnia of childhood, limit setting type Sleepwalking Sleep terrors Nighttime fears/nightmares Obstructive sleep apnea
Middle childhood (6-12 hr)	9-11 hr	School and behavior problems may be related to sleep problems Media and electronics, such as television, computer, video games, and the Internet increasingly compete for sleep time Irregularity of sleep–wake schedules reflects increasing discrepancy between school and non–school night bedtimes and wake times	Nightmares Obstructive sleep apnea Insufficient sleep
Adolescence (>12 yr)	Average sleep duration 7-7.5 hr; only 20% of adolescents overall get the recommended 9-9.25 hr of sleep Later bedtimes; increased discrepancy sleep patterns weekdays/weekends	Puberty-mediated phase delay (later sleep onset and wake times), relative to sleep-wake cycles in middle childhood Earlier required wake times Environmental competing priorities for sleep	Insufficient sleep Delayed sleep phase disorder Narcolepsy Restless legs syndrome/periodic limb movement disorder

stimulant (e.g., psychostimulants, caffeine), sleep-disrupting (e.g., corticosteroids), or daytime-sedating (some anticonvulsants, α-agonists) properties; hospitalized children; and children with a variety of psychiatric disorders, including attention-deficit/hyperactivity disorder (ADHD), depression, bipolar disorder, and anxiety disorders. Children with neurodevelopmental disorders such as blindness, mental retardation, some chromosomal syndromes (e.g., Smith-Magenis, fragile X), and autism spectrum disorders have especially high rates of sleep disturbances for a wide variety of reasons. They may be on sleep-disrupting medications, they are often more prone to nocturnal seizures, they may be less easily entrained by environmental cues and thus more vulnerable to circadian disruption, and are more likely to have

comorbid psychiatric and behavioral conditions which that further predispose them to disrupted sleep.

Insomnia of Childhood

Insomnia is difficulty initiating and/or maintaining sleep that occurs despite age-appropriate time and opportunity for sleep and results in some degree of impairment in daytime functioning for the child and/or family (ranging from fatigue, irritability, lack of energy, and mild cognitive impairment to effects on mood, school performance, and quality of life). Insomnia may be of a short-term and transient nature (usually related to an acute event), or may be characterized as long-term and chronic. Insomnia is a set of *symptoms* with a large number of possible etiologies (e.g., pain, medication, medical and psychiatric conditions, learned behaviors). Insomnia, like many behavioral issues in children, is often primarily defined by parental concerns rather than by objective criteria, and therefore should be viewed in the context of family (i.e., maternal depression, stress), child (i.e., temperament, developmental level), and environmental (i.e., cultural practices, sleeping space) considerations.

One of the most common presentations of insomnia found in infants and toddlers is the **sleep-onset association type.** In this situation, the child learns to fall asleep only under certain conditions or associations, which typically require parental presence, such as being rocked or fed, and does not develop the ability to self-soothe. During the night, when the child experiences the type of brief arousal that normally occurs at the end of an ultradian sleep cycle or awakens for other reasons, the child is not able to get back to sleep without those same associations being present. The infant then "signals" the parent by crying (or coming into the parents' bedroom, if the child is ambulatory) until the necessary associations are provided. The presenting complaint is typically one of prolonged night waking resulting in insufficient sleep (for both child and parent).

Management of night wakings should include establishment of a set sleep schedule and bedtime routine, and implementation of a behavioral program. The treatment approach typically involves a program of rapid withdrawal (extinction) or more gradual withdrawal (graduated extinction) of parental assistance at sleep onset and during the night. Extinction ("cry it out") involves putting the child to bed at a designated bedtime, "drowsy but awake" to maximize sleep propensity. and then systematically ignoring any protests by the child until a set time the next morning. Although it has considerable empirical support, extinction is often not an acceptable choice for families. Graduated extinction involves gradually weaning the child from dependence on parental presence; typically, the parent leaves the room at "lights out" and then returns or "checks" periodically at fixed or successively longer intervals during the sleep–wake transition to provide brief reassurance until the child falls asleep. The exact time interval between checks is generally determined by the parents' tolerance for crying and the child's temperament. The goal is to allow the infant or child to develop skills in self-soothing during the night, as well as at bedtime. In older infants, the introduction of more appropriate sleep associations that will be readily available to the child during the night (transitional objects, such as a blanket or toy), in addition to positive reinforcement (i.e., stickers for remaining in bed), is often beneficial. If the child has become habituated to awaken for nighttime feedings (learned hunger), then these feedings should be slowly eliminated. Parents must be consistent in applying behavioral programs to avoid inadvertent, intermittent reinforcement of night wakings; they should also be forewarned that crying behavior often temporarily escalates at the beginning of treatment (*postextinction burst*).

Bedtime problems, including stalling and refusing to go to bed, are more common in preschool-age and older children. This type of insomnia is frequently related to inadequate **limit setting** and is often the result of parental difficulties in setting limits and managing behavior in general, and the inability or unwillingness to set consistent bedtime rules and enforce a regular bedtime in particular. The situation may be exacerbated by the child's oppositional behavior. In some cases the child's resistance at bedtime is the result of an underlying problem in falling asleep that is caused by other factors (medical conditions, such as asthma or medication use; a sleep disorder, such as restless legs syndrome; or anxiety) or a mismatch between the child's intrinsic circadian rhythm ("night owl") and parental expectations regarding an "appropriate" bedtime.

Table 19-2	Basic Principles of Healthy Sleep for Children

1. **Have a set bedtime and bedtime routine** for your child.
2. **Bedtime and wake-up time should be about the same time on school nights and non–school nights.** There should not be more than about an hour difference from one day to another.
3. **Make the hour before bed shared quiet time.** Avoid high-energy activities, such as rough play, and stimulating activities, such as watching television or playing computer games, just before bed.
4. **Don't send your child to bed hungry.** A *light* snack (such as milk and cookies) before bed is a good idea. Heavy meals within an hour or 2 of bedtime, however, may interfere with sleep.
5. **Avoid products containing caffeine for at least several hours before bedtime.** These include caffeinated sodas, coffee, tea, and chocolate.
6. **Make sure your child spends time outside every day,** whenever possible, and is involved in regular exercise.
7. **Keep your child's bedroom quiet and dark.** A low-level night light is acceptable for children who find completely dark rooms frightening.
8. **Keep your child's bedroom at a comfortable temperature** during the night (<24°C [75°F]).
9. **Don't use your child's bedroom for time-out or punishment.**
10. **Keep the television set out of your child's bedroom.** Children can easily develop the bad habit of "needing" the television to fall asleep. It's also much more difficult to control your child's viewing if the set is in the bedroom.

Successful treatment of limit-setting sleep problems generally involves a combination of parent education regarding appropriate limit setting, decreased parental attention for bedtime-delaying behavior, establishment of bedtime routines, and positive reinforcement (sticker charts) for appropriate behavior at bedtime; other behavioral management strategies that have empirical support include bedtime fading (temporarily setting the bedtime closer to the actual sleep onset time and then gradually advancing the bedtime to an earlier target bedtime). Older children may benefit from being taught relaxation techniques to help themselves fall asleep more readily. Following the principles of healthy sleep practices for children is essential (Table 19-2).

When the insomnia is not primarily a result of parent behavior or secondary to another sleep disturbance, or to a psychiatric or medical problem, it is often referred to as **psychophysiologic** or **primary** or **learned insomnia**. Primary insomnia occurs largely in adolescents and is characterized by a combination of learned sleep-preventing associations and heightened physiologic arousal resulting in a complaint of sleeplessness and decreased daytime functioning. A hallmark of primary insomnia is excessive worry about sleep and an exaggerated concern of the potential daytime consequences. The physiologic arousal can be in the form of cognitive hypervigilance, such as "racing" thoughts; in many individuals with insomnia an increased baseline level of arousal is further intensified by this secondary anxiety about sleeplessness. Treatment usually involves educating the adolescent about the principles of healthy sleep practices (Table 19-3), institution of a consistent sleep–wake schedule, avoidance of daytime napping, instructions to use the bed for sleep only and to get out of bed if unable to fall asleep (stimulus control), restricting time in bed to the actual time asleep (sleep restriction), addressing maladaptive cognitions about sleep, and teaching relaxation techniques to reduce anxiety. Hypnotic medications are rarely needed.

Obstructive Sleep Apnea

Sleep-disordered breathing (SDB) in children encompasses a broad spectrum of respiratory disorders that occur exclusively in or are

Table 19-3	Basic Principles of Healthy Sleep for Adolescents

1. **Wake up and go to bed at about the same time** every night. Bedtime and wake-up time should not differ from school to non–school nights by more than approximately 1 hr.
2. **Avoid sleeping in on weekends** to "catch up" on sleep. This makes it more likely that you will have problems falling asleep.
3. If you take **naps**, they should be **short** (no more than 1 hr) and **scheduled in the early to midafternoon**. However, if you have a problem with falling asleep at night, **napping** during the day may make it worse and should be avoided.
4. **Spend time outside** every day. Exposure to sunlight helps to keep your body's internal clock on track.
5. **Exercise regularly.** Exercise may help you fall asleep and sleep more deeply.
6. **Use your bed for sleeping only.** Don't study, read, listen to music, watch television, etc., on your bed.
7. Make the 30-60 minutes before a **quiet or wind-down time**. Relaxing, calm, enjoyable activities, such as reading a book or listening to calm music, help your body and mind slow down enough to let you get to sleep. Don't study, watch exciting/scary movies, exercise, or get involved in "energizing" activities just before bed.
8. Eat regular meals and **don't go to bed hungry**. A light snack before bed is a good idea; eating a full meal in the hour before bed is not.
9. **Avoid** eating or drinking products containing **caffeine** from dinner time on. These include caffeinated sodas, coffee, tea, and chocolate.
10. **Do not use alcohol.** Alcohol disrupts sleep and may cause you to awaken throughout the night.
11. **Smoking disturbs sleep.** Don't smoke at least 1 hr before bed (and preferably, not at all!).
12. Don't use **sleeping pills, melatonin**, or other **nonprescription sleep aids** to help you sleep unless specifically recommended by your doctor. These can be dangerous, and the sleep problems often return when you stop taking the medicine.

exacerbated by sleep, and includes primary snoring and upper airway resistance syndrome, as well as apnea of prematurity (see Chapter 101.2) and central apnea (see Chapter 418). **Obstructive sleep apnea (OSA)**, the most important clinical entity within the SDB spectrum, is a respiratory disorder that is characterized by repeated episodes of prolonged upper airway obstruction during sleep despite continued or increased respiratory effort, resulting in complete (apnea) or partial (hypopnea; ≥30% reduction in airflow accompanied by ≥3% O_2 desaturation and/or arousal) cessation of airflow at the nose and/or mouth, as well as in disrupted sleep. Both intermittent hypoxia and the multiple arousals resulting from these obstructive events likely contribute to significant metabolic, cardiovascular, and neurocognitive/neurobehavioral morbidity.

Primary snoring is defined as snoring without associated ventilatory abnormalities on overnight polysomnogram (e.g., apneas or hypopneas, hypoxemia, hypercapnia) or respiratory-related arousals, and is a manifestation of the vibrations of the oropharyngeal soft tissue walls that occur when an individual attempts to breathe against increased upper airway resistance during sleep. Although generally considered nonpathologic, primary snoring in children with may still be associated with subtle breathing abnormalities during sleep, including evidence of increased respiratory effort, which, in turn, may be associated with adverse neurodevelopmental outcomes.

Etiology

OSA results from an anatomically or functionally narrowed upper airway; this typically involves some combination of decreased upper airway patency (upper airway obstruction and/or decreased upper airway diameter), increased upper airway collapsibility (reduced pharyngeal muscle tone), and decreased drive to breathe in the face of reduced upper airway patency (reduced central ventilatory drive) (Table 19-4). Upper airway obstruction varies in degree and level (i.e., nose, nasopharynx/oropharynx, hypopharynx) and is most commonly caused by adenotonsillar hypertrophy, although tonsillar size does not necessarily correlate with degree of obstruction, especially in older children. Other causes of airway obstruction include allergies associated with chronic rhinitis/nasal obstruction; craniofacial abnormalities, including hypoplasia/displacement of the maxilla and mandible; gastroesophageal reflux with resulting pharyngeal reactive edema (see Chapter 323); nasal septal deviation (see Chapter 376); and velopharyngeal flap cleft palate repair. Reduced upper airway tone may result from neuromuscular diseases, including hypotonic cerebral palsy and muscular dystrophies (see Chapter 609), or hypothyroidism (see Chapter 565). Reduced central ventilatory drive may be present in some children with Arnold-Chiari malformation (see Chapter 418), rapid-onset obesity with hypothalamic dysfunction, hypoventilation, and autonomic dysregulation, and meningomyelocele (see Chapter 591). In other situations, the etiology is mixed; individuals with Down syndrome (see Chapter 81), by virtue of their facial anatomy, hypotonia, macroglossia, and central adiposity, as well as the increased incidence of hypothyroidism, are at particularly high risk for OSA, with some estimates of as great as 70% prevalence.

Table 19-4	Anatomic Factors That Predispose to Obstructive Sleep Apnea and Hypoventilation in Children

NOSE
Anterior nasal stenosis
Choanal stenosis/atresia
Deviated nasal septum
Seasonal or perennial rhinitis
Nasal polyps, foreign body, hematoma, mass lesion

NASOPHARYNGEAL AND OROPHARYNGEAL
Adenotonsillar hypertrophy
Macroglossia
Cystic hygroma
Velopharyngeal flap repair
Cleft palate repair
Pharyngeal mass lesion

CRANIOFACIAL
Micrognathia/retrognathia
Midface hypoplasia (e.g., trisomy 21, Crouzon, Apert syndrome)
Mandibular hypoplasia (Pierre Robin sequence, Treacher Collins, Cornelia de Lange)
Craniofacial trauma
Skeletal and storage diseases
Achondroplasia
Storage diseases (e.g., glycogen, Hunter, Hurler syndrome)

Although many children with OSA are of normal weight, an increasingly large percentage are overweight or obese, and many of these children are school-age and younger (see Chapter 47). There is a significant correlation between weight and SDB (e.g., habitual snoring, OSA, sleep-related hypoventilation). Although adenotonsillar hypertrophy also plays an important etiologic role in overweight/obese children with OSA, mechanical factors related to an increase in the amount of adipose tissue in the throat (pharyngeal fat pads), neck (increased neck circumference), and chest wall and abdomen can create increased upper airway resistance, worsen gas exchange, and increased work of breathing, particularly in the supine position and during REM sleep. There may be a component of blunted central ventilatory drive in response to hypoxia/hypercapnia and hypoventilation as well (see Chapter 418.3), particularly in children with morbid or syndrome-based (e.g., Prader-Willi) obesity. Overweight and obese children and adolescents are at a particularly high risk for metabolic and cardiovascular complications of SDB, such as insulin resistance and systemic hypertension; morbidly obese children are also be at increased risk for postoperative complications as well as residual OSA following adenotonsillectomy.

Epidemiology

Overall prevalence of parent-reported snoring in the pediatric population is approximately 8%; "always" snoring is reported in 1.5-6%, and "often" snoring in 3-15%. When defined by parent-reported symptoms, the prevalence of OSA is 4-11%. The prevalence of pediatric OSA as documented by overnight sleep studies utilizing ventilatory monitoring procedures (e.g., in-lab polysomnography [PSG], home studies) is 1-4% overall, with a reported range of 0.1-13%. Prevalence is also affected by the demographic characteristics, such as age (increased prevalence between 2 and 8 yr), gender (more common in boys, especially after puberty), race/ethnicity (increased prevalence in African-American and Asian children), history of prematurity, and family history of OSA.

Pathogenesis

The upregulation of inflammatory pathways, as indicated by an increase in peripheral markers of inflammation such as C-reactive protein, appear to be linked to metabolic dysfunction (e.g., insulin resistance, dyslipidemia) in both obese and nonobese children with OSA. Both systemic inflammation and arousal-mediated increases in sympathetic autonomic nervous system activity with altered vasomotor tone may be key contributors to increased cardiovascular risk in both adults and children with OSA. Mechanical stress on the upper airway induced by chronic snoring may also result in both local mucosal inflammation of adenotonsillar tissues and subsequent upregulation of inflammatory molecules, most notably leukotrienes. Another potential mechanism that may mediate cardiovascular sequelae in both adults and children with OSA is altered endothelial function.

One of the primary mechanisms by which OSA is believed to exert negative influences on cognitive function appears to involve repeated episodic arousals from sleep leading to sleep fragmentation and resulting sleepiness. An equally important role may be intermittent hypoxia that leads directly to systemic inflammatory vascular changes in the brain. Levels of inflammatory markers such as C-reactive protein and cytokine interleukin-6 are elevated in children with OSA and are also associated with cognitive dysfunction.

Clinical Manifestations

The clinical manifestations of OSA may be divided into sleep-related and daytime symptoms. The most common nocturnal manifestations of OSA in children and adolescents are loud, frequent, and disruptive snoring, breathing pauses, choking or gasping arousals, restless sleep, and nocturnal diaphoresis. Many children who snore do not have OSA, but very few children with OSA do not snore. Children, like adults, tend to have more frequent and more severe obstructive events in REM sleep and when sleeping in the supine position. Children with OSA may adopt unusual sleeping positions, keeping their necks hyperextended to maintain airway patency. Frequent arousals associated with obstruction may result in nocturnal awakenings, but are more likely to cause fragmented sleep.

Daytime symptoms of OSA include mouth breathing and dry mouth, chronic nasal congestion/rhinorrhea, hyponasal speech, morning headaches, difficulty swallowing, and poor appetite. Children with OSA may have secondary enuresis, which has been postulated to result from the disruption of the normal nocturnal pattern of antidiuretic hormone or atrial natriuretic peptide secretion. Partial arousal parasomnias (sleepwalking and sleep terrors) may occur more frequently in children with OSA, related to the frequent associated arousals and an increased percentage of SWS.

One of the most important but frequently overlooked sequelae of OSA in children is the effect on mood, behavior, learning, and academic functioning. The neurobehavioral consequences of OSA in children include daytime sleepiness with drowsiness, difficulty in morning waking, and unplanned napping or dozing off during activities, although evidence of frank hypersomnolence tends to be less common in children compared to adults with OSA (except in very obese children). Mood changes include increased irritability, mood instability and emotional dysregulation, low frustration tolerance, and depression/anxiety. Behavioral issues include both "internalizing" (i.e., increased somatic complaints and social withdrawal) and "externalizing" behaviors, including aggression, impulsivity, hyperactivity, oppositional behavior, and conduct problems. There is a substantial overlap between the clinical impairments associated with OSA and the diagnostic criteria for ADHD, including inattention, poor concentration, and distractibility (see Chapter 33). There may be a selective impact of OSA specifically on "executive functions," which include cognitive flexibility, task initiation, self-monitoring, planning, organization, and self-regulation of affect and arousal; executive function deficits are also a hallmark of ADHD.

Many of the studies that have looked at changes in behavior and neuropsychologic functioning in children following treatment (usually adenotonsillectomy) for OSA have largely documented significant improvement in outcomes, in both the short and long term, of OSA syndrome posttreatment, including daytime sleepiness, mood, behavior, academics, and quality of life. However, most studies failed to find a dose-dependent relationship between OSA in children and specific neurobehavioral/neurocognitive deficits, suggesting that other factors may influence neurocognitive outcomes, including individual genetic susceptibility, racial/ethnic background, environmental influences such as passive smoking exposure, and comorbid conditions, such as obesity, shortened sleep duration, and the presence of other sleep disorders. In adults, cognitive functions impacted by OSA include deficits in attention, long-term visual and verbal memory, visuospatial functioning, and executive function while language and psychomotor function do not appear to be impacted.

Diagnosis

The 2012 revised American Academy of Pediatrics clinical practice guidelines provide excellent information for the evaluation and management of uncomplicated childhood OSA (Table 19-5). There are no physical examination findings that are truly pathognomonic for OSA, and most healthy children with OSA appear normal; certain physical examination findings may suggest OSA. Growth parameters may be abnormal (obesity or, less commonly, failure to thrive), and there may be evidence of chronic nasal obstruction (hyponasal speech, mouth breathing, septal deviation, "adenoidal facies"), as well as signs of atopic disease (i.e., "allergic shiners"). Oropharyngeal examination may reveal enlarged tonsils, excess soft tissue in the posterior pharynx, and a narrowed posterior pharyngeal space. Any abnormalities of the facial structure, such as retrognathia and/or micrognathia, midfacial hypoplasia, best appreciated by inspection of the lateral facial profile, increase the likelihood of OSA and should be noted. In very severe cases, there may be evidence of pulmonary hypertension, right-sided heart failure, and cor pulmonale; systemic hypertension may occur, especially in obese children.

Because no combination of clinical history and physical findings can accurately predict which children with snoring have OSA, the gold standard for diagnosing OSA remains an in-lab overnight **polysomnogram**.

Overnight PSG is a technician-supervised, monitored study that documents physiologic variables during sleep; sleep staging, arousal measurement, cardiovascular parameters, and body movements (electroencephalography, electrooculography, chin and leg electromyography, electrocardiogram, body position sensors, and video recording), and a combination of breathing monitors (oronasal thermal sensor and nasal air pressure transducer for airflow), chest/abdominal monitors (e.g., inductance plethysmography for respiratory effort, pulse oximeter for O_2 saturation, end-tidal or transcutaneous CO_2 for CO_2 retention, snore microphone). The polysomnographic parameter most commonly used in evaluating for sleep disordered breathing is the apnea-hypopnea index (AHI), which indicates the number of apneic and hypopneic events per hour of sleep. It should be noted that currently there are no universally accepted polysomnographic normal reference values and parameters for diagnosing OSA in children, and it is still unclear which parameters best predict morbidity. Normal preschool and school-age children generally have a total AHI of less than 1.5 (obstructive AHI <1), and this is the most widely used cutoff value for OSA in children 12 yr and below; in older adolescents, the adult cutoff of an AHI ≥5 is generally used. In cases in which the AHI

Table 19-5 American Academy of Pediatrics Clinical Practice Guideline: Diagnosis and Management of Childhood Obstructive Sleep Apnea Syndrome (September 2012)
Key Action Statement 1: Screening for OSAS As part of routine health maintenance visits, clinicians should inquire whether the child or adolescent snores. If the answer is affirmative or if a child or adolescent presents with signs or symptoms of OSAS, clinicians should perform a more focused evaluation. (Evidence Quality: Grade B; Recommendation Strength: Recommendation.)
Key Action Statement 2A: Polysomnography If a child or adolescent snores on a regular basis and has any of the complaints or findings of OSAS, clinicians should either (1) obtain a polysomnogram (Evidence Quality A; Key Action strength: Recommendation) *or* (2) refer the patient to a sleep specialist or otolaryngologist for a more extensive evaluation (Evidence quality D; Key Action strength: Option). (Evidence Quality: Grade A for polysomnography, Grade D for specialist referral; Recommendation Strength: Recommendation.)
Key Action Statement 2B: Alternative Testing If polysomnography is not available, then clinicians may order alternative diagnostic tests, such as nocturnal video recording, nocturnal oximetry, daytime nap polysomnography, or ambulatory polysomnography. (Evidence Quality: Grade C; Recommendation Strength: Option.)
Key Action Statement 3: Adenotonsillectomy If a child is determined to have OSAS, has a clinical examination consistent with adenotonsillar hypertrophy, and does not have a contraindication to surgery, the clinician should recommend adenotonsillectomy as the first line of treatment. If the child has OSAS but does not have adenotonsillar hypertrophy, other treatment should be considered (see Key Action Statement 6). Clinical judgment is required to determine the benefits of adenotonsillectomy compared with other treatments in obese children with varying degrees of adenotonsillar hypertrophy. (Evidence Quality: Grade B; Recommendation Strength: Recommendation.)
Key Action Statement 4: High-Risk Patients Undergoing Adenotonsillectomy Clinicians should monitor high-risk patients undergoing adenotonsillectomy as inpatients postoperatively. (Evidence Quality: Grade B; Recommendation Strength: Recommendation.)
Key Action Statement 5: Reevaluation Clinicians should clinically reassess all patients with OSAS for persisting signs and symptoms after therapy to determine whether further treatment is required. (Evidence Quality: Grade B; Recommendation Strength: Recommendation.)
Key Action Statement 5B: Reevaluation of High-Risk Patients Clinicians should reevaluate high-risk patients for persistent OSAS after adenotonsillectomy, including those who had a significantly abnormal baseline polysomnogram, have sequelae of OSAS, are obese, or remain symptomatic after treatment, with an objective test (see Key Action Statement 2) or refer such patients to a sleep specialist. (Evidence Quality: Grade B; Recommendation Strength: Recommendation.)
Key Action Statement 6: CPAP Clinicians should refer patients for CPAP management if symptoms/signs or objective evidence of OSAS persists after adenotonsillectomy or if adenotonsillectomy is not performed. (Evidence Quality: Grade B; Recommendation Strength: Recommendation.)
Key Action Statement 7: Weight Loss Clinicians should recommend weight loss in addition to other therapy if a child/adolescent with OSAS is overweight or obese. (Evidence Quality: Grade C; Recommendation Strength: Recommendation.)
Key Action Statement 8: Intranasal Corticosteroids Clinicians may prescribe topical intranasal corticosteroids for children with mild OSAS in whom adenotonsillectomy is contraindicated or for children with mild postoperative OSAS. (Evidence Quality: Grade B; Recommendation Strength: Option.)

Adapted from Marcus CL, Brooks LJ, Draper KA, et al: Diagnosis and management of childhood obstructive sleep apnea syndrome. *Pediatrics* 130:576-584, 2012.

is between 1 and 5 obstructive events per hour, clinical judgment regarding risk factors for SDB, evidence of daytime sequelae, and the technical quality of the overnight sleep study should determine further management.

Treatment

There are presently no universally accepted guidelines regarding the indications for treatment of pediatric SDB (i.e., including primary snoring and OSA). Current recommendations largely emphasize weighing what is known about the potential cardiovascular, metabolic, and neurocognitive sequelae of SDB in children in combination with the individual healthcare professional's clinical judgment. The decision of whether and how to treat OSA specifically in children is contingent on a number of parameters, including severity (nocturnal symptoms, daytime sequelae, sleep study results), duration of disease, and individual patient variables such as age, comorbid conditions, and underlying etiologic factors. Figure 19-1 presents a guide to decision making. In the case of moderate (AHI 5-10) to severe disease (AHI >10), the decision to treat is usually straightforward, and most pediatric sleep experts recommend that any child with an apnea hypopnea index >5 should be treated. However, a large randomized trial of early adenotonsillectomy vs watchful waiting with supportive care, 46% of the control group children normalized on PSG (compared to 79% of the early adenotonsillectomy group) during the 7 mo observation period.

In the majority of cases of pediatric OSA, adenotonsillectomy is the first-line treatment in any child with significant adenotonsillar hypertrophy, even in the presence of additional risk factors such as obesity. Adenotonsillectomy in uncomplicated cases generally (70-90% of children) results in complete resolution of symptoms; regrowth of adenoidal tissue after surgical removal occurs in some cases. Groups considered high-risk include young children (<3 yr old), as well as those with severe OSA documented by PSG, significant clinical sequelae of OSA (e.g., failure to thrive), or associated medical conditions, such as craniofacial syndromes, morbid obesity, and hypotonia. All patients should be reevaluated postoperatively to determine whether additional evaluation, a repeat polysomnogram and/or treatment are required. The American Academy of Sleep Medicine recommends that in high-risk groups (children with obesity, craniofacial anomalies, Down syndrome or moderate-severe OSA) or in children with continued symptoms of OSA, a follow-up sleep study at least 6 wk postadenotonsillectomy is indicated.

Additional treatment measures that may be appropriate include weight loss, positional therapy (attaching a firm object, such as a tennis ball, to the back of a sleep garment to prevent the child from sleeping in the supine position), and aggressive treatment of additional risk factors when present, such as asthma, seasonal allergies, and gastroesophageal reflux; there is evidence that intranasal corticosteroids and leukotriene inhibitors may be helpful in reducing upper airway inflammation in mild OSA. Other surgical procedures, such as

Algorithm for the Diagnosis and Treatment of Pediatric OSA

Step 1. Child is at risk for OSA (one or more):

- Parents report symptoms of OSA
- Physician identifies symptoms of OSA using structured questionnaire
- Conditions predisposing to OSA are present (adenotonsillar hypertrophy-allergic rhinitis, obesity, craniofacial abnormalities, neuromuscular disorders)
- History of prematurity
- Family history of OSA

Step 2a. OSA-related morbidity is recognized (one or more):

- Systolic or diastolic blood pressure >95th percentile for gender, age and height, or pulmonary hypertension
- Daytime sleepiness, hyperactivity, inattention, academic difficulties
- Inadequate somatic growth
- Enuresis

Step 2b. Conditions frequently coexisting with OSA are identified (one or more):

- Recurrent otitis media, tympanostomy tubes
- Recurrent wheezing
- Oral-motor dysfunction
- Metabolic syndrome

Step 3. Factors predicting OSA persistence are present (at least one):

- Male gender
- Increasing Body Mass Index percentile, development of obesity

Step 4. Objective evaluation for OSA severity:

- Overnight polysomnography
- If not available: nocturnal pulse oximetry

Step 5. Child is a potential candidate for treatment if at risk for OSA (step 1) and at least one criterion:

- AHI >5 episodes/h
- AHI 1–5 and OSA morbidity present (step 2a)
- AHI 1–5 and risk factor for OSA persistence (step 3)
- AHI 1–5 and neuromuscular disorder or craniofacial abnormalities present (step 1)
- ≥ 3 SpO_2 drops $<90\%$ and ≥ 3 clusters of desaturation events <u>or</u> alternatively, desaturation ($\geq 3\%$) index ≥ 3.5 episodes/h

Or if polysomnography or oximetry not available:

- Frequently or almost always loud snoring and male gender
- Frequently or almost always loud snoring and sleepiness
- Frequently or almost always loud snoring and learning problems

Priority for treatment increases if coexisting OSA-related conditions are present that may also improve with treatment (step 2b)

Step 6. <u>Stepwise</u> treatment approach:

1. Weight control for obesity
2. Trial of nasal corticosteroids for adenoidal hypertrophy prior to adenoidectomy
3. Adenotonsillectomy for adenotonsillar hypertrophy
4. Orthodontic devices for mandibular malpositioning, narrow maxilla
5. nCPAP for: i) residual OSA after adenotonsillectomy; ii) OSA related to obesity, neuromuscular disorders or craniofacial abnormalities and unresponsive to other measures
6. Craniofacial surgery or tracheostomy if other treatment modalities fail

Notes

1. Information collected in steps 1–4 is used to identify children requiring treatment for OSA (step 5) and to determine the appropriate therapeutic modalities (step 6). Please refer to the text for details.
2. Step 6 represents a hierarchical approach to OSA treatment.

Figure 19-1 Algorithm for the diagnosis and treatment of pediatric OSA. *(From Kaditis A, Kheirandish-Gozal L, Gozal D: Algorithm for the diagnosis and treatment of pediatric OSA: a proposal of two pediatric sleep centers,* Sleep Med *13(3):217–227, 2012, Figure 1.)*

uvulopharyngopalatoplasty, and maxillofacial surgery (e.g., mandibular distraction osteogenesis), are seldom performed in children. Oral appliances, such as mandibular advancing devices and palatal expanders, may be considered in select cases; consultation with a pediatric dentist/orthodontist is recommended. Exercises to address abnormal tongue position and low upper airway tone (i.e., myofunctional therapy) have been shown to be of some benefit in mild cases of OSA.

Continuous or bilevel positive airway pressure is the most common treatment for OSA in adults and can be used successfully in children and adolescents. Positive airway pressure may be recommended if removing the adenoids and tonsils is not indicated, if there is residual disease following adenotonsillectomy, or if there are major risk factors that are not amenable to treatment with surgery (obesity, hypotonia). Positive airway pressure delivers humidified, warmed air through an interface (mask, nasal pillows) that, under pressure, effectively “splints” the upper airway open. Optimal pressure settings (that abolish or significantly reduce respiratory events without increasing arousals or central apneas) are determined in the sleep lab during a full night positive airway pressure titration. Careful attention should be paid to education of the child and family and desensitization protocols should be implemented in most cases to increase the likelihood of adherence. Efficacy studies at the current pressure and retitrations should be conducted periodically with long-term use (at least annually or in association with significant weight changes or resumption of SDB symptoms).

Parasomnias

Parasomnias are episodic nocturnal behaviors that often involve cognitive disorientation and autonomic and skeletal muscle disturbance. Parasomnias may be further characterized as occurring primarily during non-REM sleep (partial arousal parasomnias) or in association with REM sleep, including nightmares, hypnogogic hallucinations, and sleep paralysis; other common parasomnias include sleep-talking and hypnic jerks or “sleep starts” (Fig. 19-2). Sleep-related movement disorders, including restless legs syndrome/periodic limb movement disorder (RLS/PLMD) and rhythmic movement disorder (head banging, body rocking), are reviewed in “Sleep-Related Movement Disorders: Restless Legs Syndrome/Periodic Limb Movement Disorder and Rhythmic Movements” below.

Etiology

Partial arousal parasomnias, which include **sleepwalking, sleep terrors**, and **confusional arousals** are more common in preschool and school-age children because of the relatively higher percentage of SWS in younger children. They typically occur when SWS predominates (i.e., in the first third of the night); in contrast, nightmares, which are much more common than the partial arousal parasomnias but are often confused with them, are concentrated in the last third of the night, when REM sleep is most prominent. Any factor that is associated with an increase in the relative percentage of SWS (certain medications, previous sleep restriction) may increase the frequency of events

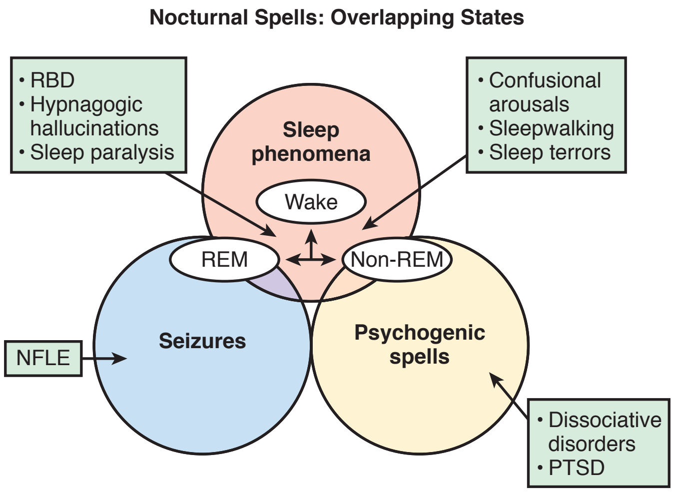

Figure 19-2 **Overlapping states of being.** Parasomnias are explainable on the basic notion that sleep and wakefulness are not mutually exclusive states but may dissociate and oscillate rapidly. The abnormal admixture of the 3 states of being (non-REM sleep, REM sleep, and wakefulness) may overlap, giving rise to parasomnias. REM parasomnias occur because of the abnormal intrusion of wakefulness into REM sleep and likewise non-REM parasomnias, such as sleepwalking, occur because of abnormal intrusions of wakefulness into non-REM sleep. Other nocturnal spells that may be confused with parasomnias include NFLE and psychogenic spells such as posttraumatic stress disorder (PTSD), dissociated disorders. AHI, Apnea–hypopnea index (mean number of central + mixed + obstructive apneas and hypopneas per hour of total sleep); NFLE, nocturnal frontal lobe epilepsy; RBD, REM behavior disorder. *(Modified from Mahowald MW, Schenck CH. Non-rapid eye movement sleep parasomnias.* Neurol Clin *23(4):1078, vii, 2005.)*

in a predisposed child. There appears to be a genetic predisposition for both sleepwalking and night terrors. Partial arousal parasomnias may also be difficult to distinguish from nocturnal seizures. Table 19-6 summarizes similarities and differences among these nocturnal arousal events.

Epidemiology

Many children (15-40%) **sleepwalk** on at least 1 occasion; the prevalence of children who regularly sleepwalk is approximately 17%, and 3-4% have frequent episodes. Sleepwalking (somnambulism) may persist into adulthood, with the prevalence in adults of approximately 4%. The prevalence is approximately 10 times greater in children with a family history of sleepwalking. Approximately 1-3% of children experience **sleep terrors**, primarily during the preschool and elementary school yr, and the age at onset is usually between 4 and 12 yr. Because of the common genetic predisposition, the prevalence of sleep terrors in children who sleepwalk is approximately 10%. Although sleep terrors can occur at any age from infancy through adulthood, most individuals outgrow sleep terrors by adolescence. **Confusional arousals** (sleep drunkenness, sleep inertia) commonly co-occur with sleepwalking and sleep terrors; prevalence rates have been estimated to be upward of 15% in children ages 3-13 yr.

Clinical Manifestations

The partial arousal parasomnias have several features in common. Because they typically occur at the transition out of "deep" or SWS, partial arousal parasomnias have clinical features of both the awake (ambulation, vocalizations) and the sleeping (high arousal threshold, unresponsiveness to the environment) states; there is usually amnesia for the events. The duration is typically a few minutes (sleep terrors) to 30-40 minutes (confusional arousals). Sleep terrors are sudden in onset and characteristically involve a high degree of autonomic arousal (i.e., tachycardia, dilated pupils), whereas confusional arousals typically arise more gradually from sleep, may involve thrashing around but usually not displacement from bed, and are often accompanied by slow mentation, disorientation and confusion on forced arousal from SWS or upon waking in the morning. Sleepwalking may be associated with safety concerns (e.g., falling out of windows, wandering outside). Avoidance of, or increased agitation with, comforting by parents or attempts at awakening are also common features of all partial arousal parasomnias.

REM sleep behavior disorder, is characterized by episodes of arousal during REM sleep, loss of REM atonia, and acting out of dreams including vocalizations during night-time sleep or naps. Some patients have CNS lesions (tumors), narcolepsy, seizures, neuropsychiatric medications, or neurodegenerative diseases.

Treatment

Management of partial arousal parasomnias involves some combination of parental education and reassurance, healthy sleep practices, and avoidance of exacerbating factors such as sleep restriction and caffeine. Particularly in the case of sleepwalking, it is important to institute safety precautions such as use of gates in doorways and at the top of staircases, locking of outside doors and windows, and installation of parent notification systems such as bedroom door alarms. Scheduled awakenings, a behavioral intervention that involves having the parent wake the child approximately 15-30 min before the time of night that the first parasomnia episode is most likely to be successful in situations in which partial arousal episodes occur on a nightly basis. Pharmacotherapy is rarely necessary, but may be indicated in cases of frequent or severe episodes, high risk of injury, violent behavior, or serious disruption to the family; the primary pharmacologic agents used are potent SWS suppressants, primarily benzodiazepines and tricyclic antidepressants.

Sleep-Related Movement Disorders: Restless Legs Syndrome/Periodic Limb Movement Disorder and Rhythmic Movements

RLS (Willis Ekbom syndrome) is a chronic neurologic disorder, characterized by an almost irresistible urge to move the legs, often accompanied by uncomfortable sensations in the lower extremities. Both the urge to move and the sensations are usually worse at rest and in the evening and are at least partially relieved by movement, including walking, stretching, and rubbing, but only as long as the motion continues. RLS is a clinical diagnosis that is based on the presence of these key symptoms. PLMD is characterized by periodic, repetitive, brief (0.5-10 sec), and highly stereotyped limb jerks typically occurring at 20-40 sec intervals. These movements occur primarily during sleep, most commonly occur in the legs, and frequently consist of rhythmic extension of the big toe and dorsiflexion at the ankle. The diagnosis of **periodic limb movements** (PLMs) requires overnight PSG to document the characteristic limb movements with anterior tibialis electromyography leads.

Etiology

"Early-onset" RLS (i.e., onset of symptoms before 35-40 yr of age), often termed "primary" RLS, appears to have a particularly strong genetic component, with a 6-7 fold increase in prevalence in first-degree relatives of RLS patients. The mode of inheritance is complex and several genetic loci have been identified (*MEIS1, BTBD9, MAP2K5*). Low serum iron levels in both adults and children may be an important etiologic factor for the presence and severity of both RLS symptoms and PLMs. As a marker of decreased iron stores, serum ferritin levels in both children and adults with RLS are frequently low (i.e., less than 50 µg/mL). The underlying mechanism that has been postulated is related to the role of iron as a cofactor in tyrosine hydroxylation, a rate-limiting step in dopamine synthesis; in turn, dopaminergic dysfunction has been implicated as playing a key role particularly in the genesis of the sensory component of RLS, as well as in PLMD. Certain medical conditions, including diabetes mellitus, end-stage renal disease, cancer, rheumatoid arthritis, hypothyroidism, and pregnancy, may also be associated with RLS/PLMD, as are specific medications

Table 19-6 Key Similarities and Differentiating Features Between Non-REM and REM Parasomnias as Well as Nocturnal Seizures

	CONFUSIONAL AROUSALS	SLEEP TERRORS	SLEEPWALKING	NIGHTMARES	RBD	NOCTURNAL SEIZURES

(e.g., antihistamines such as diphenhydramine, antidepressants, and H_2 blockers such as cimetidine) and substances (notably, caffeine).

Epidemiology

Previous studies found prevalence rates of RLS in the pediatric population ranging from 1-6%; approximately 2% of 8-17 yr olds meet the criteria for "definite" RLS. Prevalence rates of PLMs greater than 5 per hour in clinical populations of children referred for sleep studies range from 5-27%; in survey studies of PLM symptoms, rates are 8-12%. Several studies in referral populations have found that PLMs occur in as much as 25% of children diagnosed with ADHD.

Clinical Manifestations

In addition to the urge to move the legs and the sensory component, most RLS episodes begin or are exacerbated by rest or inactivity, such as lying in bed to fall asleep or riding in a car for prolonged periods. A unique feature of RLS is that the timing of symptoms also appears to have a circadian component, in that they often peak in the evening hours. Some children may complain of "growing pains," although this is considered a nonspecific feature. Because RLS symptoms are usually worse in the evening, bedtime struggles and difficulty falling asleep are 2 of the most common presenting complaints. In contrast to patients with RLS, individuals with PLMs are usually unaware of these movements, but children may complain of morning muscle pain or fatigue; these movements may result in arousals during sleep and consequent significant sleep disruption. Parents of children with RLS/PLMD may report that their child is a restless sleeper, moves around or even falls out of bed during the night.

Treatment

The decision of whether and how to treat RLS depends on the level of severity (intensity, frequency, and periodicity) of sensory symptoms, the degree of interference with sleep, and the impact of daytime sequelae in a particular child or adolescent. With PLMs, for an index (PLMs per hour) less than 5, usually no treatment is recommended; for an index greater than 5, the decision to specifically treat PLMs should be based on the presence or absence of nocturnal symptoms (restless or nonrestorative sleep) and daytime clinical sequelae. The acronym AIMS represents a comprehensive approach to the treatment of RLS: A = avoidance of exacerbating factors such as caffeine and drugs which increase symptoms, I = iron supplementation when appropriate, M = muscle activity (increased physical activity, muscle relaxation, application of heat/cold compresses), and S = sleep (regular sleep schedule and sufficient sleep for age). Iron supplements should be instituted if serum ferritin levels are <50; it should be kept in mind that ferritin is an acute-phase reactant and thus may be falsely elevated (i.e., normal) in the setting of a concomitant illness. The recommended dose of ferrous sulfate is typically in the range of 3-6 mg/kg/day for a duration of 3 mo. Medications that increase dopamine levels in the CNS, such as ropinirole and pramipexole, have been found to be effective in relieving RLS/PLMD symptoms in adults; data in children are extremely limited.

Sleep-related rhythmic movements, including head banging, body rocking, and head rolling, are characterized by repetitive, stereotyped, and rhythmic movements or behaviors that involve large muscle groups. These behaviors typically occur with the transition at sleep at bedtime, but also at nap times and following nighttime arousals. Children typically engage in these behaviors as a means of soothing themselves to (or back to) sleep; they are much more common in the 1st yr of life and usually disappear by preschool age. In most instances, rhythmic movement behaviors are benign, because sleep is not significantly disrupted as a result of these movements and associated significant injury is rare. These behaviors typically occur in normally developing children, and in the vast majority of cases their presence does not indicate that there is some underlying neurologic or psychologic problem. Usually, the most important aspect in management of sleep-related rhythmic movements is reassurance to the family that this behavior is normal, common, benign, and self-limited.

Narcolepsy

Hypersomnia is a clinical term that is used to describe a group of disorders characterized by recurrent episodes of **excessive daytime sleepiness (EDS)**, reduced baseline alertness, and/or prolonged nighttime sleep periods that interfere with normal daily functioning. It is important to recognize that there are many potential causes of EDS, which may be broadly grouped as "extrinsic" (e.g., secondary to insufficient and/or fragmented sleep) or "intrinsic" (e.g., resulting from an increased need for sleep). **Narcolepsy** is a chronic lifelong CNS disorder, typically presenting in adolescence and early adulthood, that is characterized by profound daytime sleepiness and resultant significant functional impairment. Other symptoms frequently associated with narcolepsy, including cataplexy (sudden and temporary loss of muscle tone), hypnogogic/hypnopompic (immediately before falling asleep/awakening) hallucinations, and sleep paralysis, may be conceptualized

as representing the "intrusion" of REM sleep features into the waking state (see further descriptions below).

Etiology

The genesis of narcolepsy with cataplexy (type 1) is thought to be related to a specific deficit in the hypothalamic orexin/hypocretin neurotransmitter system. The underlying pathogenesis of narcolepsy involves selective loss of cells that secrete hypocretin/orexin in the lateral hypothalamus; it has been postulated that autoimmune mechanisms, possibly triggered by viral infections, in combination with a genetic predisposition and environmental factors, may be involved. Human leukocyte antigen testing also shows a strong association with narcolepsy; however, the vast majority of individuals with this antigen do not have narcolepsy, and most (90%), but not all, patients with narcolepsy with cataplexy are HLA-DQB1*0602–positive. Patients with narcolepsy without cataplexy (type 2) are increasingly thought to have a significantly different pathophysiology; they are much less likely to be HLA-DQB1*0602–positive. Although the majority of cases of narcolepsy are considered idiopathic, "secondary" narcolepsy with cataplexy is associated with CNS insults, including hypothalamic tumors and cranial irradiation, and specific genetic syndromes (Prader-Willi [see Chapter 81.8] and Niemann-Pick type C [see Chapter 86.4]). Narcolepsy has been reported in Finnish children after immunization with the AS03 adjuvanted AH1N1 influenza vaccine.

Epidemiology

The prevalence of narcolepsy is reported to be between 3 and 16 per 10,000, with the prevalence of narcolepsy with cataplexy approximately 0.2-0.5/10,000. The risk of developing narcolepsy with cataplexy in a 1st-degree relative of a narcoleptic patient is estimated at 1-2%; this represents an increase of 10-40–fold compared to the general population.

Clinical Manifestations and Diagnosis

The typical onset of symptoms of narcolepsy is in adolescence and early adulthood, although symptoms may initially present in school-age and even younger children. The early manifestations of narcolepsy are often ignored, misinterpreted, or misdiagnosed as other medical, neurologic, and psychiatric conditions, and the appropriate diagnosis is frequently delayed for a number of years.

The most prominent clinical manifestation of narcolepsy is profound daytime sleepiness, characterized by both an increased baseline level of daytime drowsiness and by the repeated occurrence of sudden and unpredictable sleep episodes. These "**sleep attacks**" are often described as "irresistible" in that the child or adolescent is unable to stay awake despite considerable effort, and they occur even in the context of normally stimulating activities (e.g., during meals, in the middle of a conversation). Very brief (several seconds) sleep attacks may also occur in which the individual may "stare off," appear unresponsive, or continue to engage in an ongoing activity (automatic behavior). EDS may also be manifested by increased nighttime sleep needs and extreme difficulty waking in the morning or after a nap. **Cataplexy** is considered pathognomonic for narcolepsy. Cataplexy is rarely the first symptom of narcolepsy, but it often develops within the 1st yr of the onset of EDS. It is described as an abrupt, bilateral, partial (especially knees and head/jaw) or complete loss of muscle tone, without loss of consciousness, classically triggered by an intense positive emotion (e.g., laughter, surprise). The cataplectic attacks are typically brief (seconds to minutes) but in children may last for hours or days ("status cataplecticus"), and they are fully reversible, with complete recovery of normal tone when the episode ends. "Cataplectic facies" is a clinical feature unique to the pediatric population and is characterized by slack facial musculature, a protruding tongue, and slurred speech. **Hypnogogic/hypnopompic hallucinations** involve vivid visual, auditory, and sometimes tactile sensory experiences occurring during transitions between sleep and wakefulness, primarily at sleep offset (hypnopompic) and sleep onset (hypnogogic). **Sleep paralysis** is the inability to move or speak for a few seconds or minutes at sleep onset or offset, and often accompanies the hallucinations. Other symptoms associated with narcolepsy include disrupted nocturnal sleep, impaired cognition, inattention, and behavioral and mood dysregulation.

Overnight PSG followed by a multiple sleep latency test are strongly recommended components of the evaluation of a patient with profound unexplained daytime sleepiness or suspected narcolepsy. The purpose of the overnight PSG is to evaluate for primary sleep disorders, such as OSA that may cause EDS. The multiple sleep latency test involves a series of 5 opportunities to nap (20 min long), during which narcoleptics demonstrate a pathologically shortened mean sleep onset latency (typically less than 5 minutes) as well as at least 2 periods of REM sleep occurring immediately after sleep onset.

Treatment

An individualized narcolepsy treatment plan usually involves education, good sleep hygiene, behavioral changes, and medication. Scheduled naps are often helpful. Medications such as psychostimulants and modafinil are often prescribed to control the EDS, whereas antidepressants (serotonin reuptake inhibitors, venlafaxine) may also be used to reduce cataplexy. Sodium oxybate is a drug that appears to both positively impact daytime sleepiness and REM-associated phenomena, such as cataplexy, hypnogogic hallucinations, and sleep paralysis. Most of these medications are not approved for use in children. The goal should be to allow the fullest possible return of normal functioning in school, at home, and in social situations.

Delayed Sleep Phase Disorder

Delayed sleep phase disorder (DSPD), a circadian rhythm disorder, involves a significant, persistent, and intractable phase shift in sleep–wake schedule (later sleep onset and wake time) that conflicts with the individual's normal school, work, and/or lifestyle demands. DSPD may occur at any age, but is most common in adolescents and young adults.

Etiology

Individuals with DSPD often start out as night owls; that is, they have an underlying predisposition or circadian preference for staying up late at night and sleeping late in the morning, especially on weekends, holidays, and summer vacations. The underlying pathophysiology of DSPD is still unknown, although some authors have theorized that it involves an intrinsic abnormality in the circadian oscillators that govern the timing of the sleep period.

Epidemiology

Studies indicate that the prevalence of DSPD may be as high as 7-16% in adolescents and young adults.

Clinical Manifestations

The most common clinical presentation is sleep initiation insomnia when the individual attempts to fall asleep at a "socially acceptable" desired bedtime, accompanied by extreme difficulty getting up in the morning even for desired activities, and daytime sleepiness. Sleep maintenance is generally not problematic, and no sleep onset insomnia is experienced if bedtime coincides with the preferred sleep onset time (e.g., on weekends, school vacations). School tardiness and frequent absenteeism with a decline in academic performance are often present.

Treatment

The treatment of DSPD usually has 3 components, all directed toward the goals of shifting the sleep–wake schedule to an earlier more desirable time, and maintaining the new schedule. The initial step involves shifting the sleep–wake schedule to the desired earlier times, usually with gradual (i.e., in 15-30 min increments every few days) advancement of bedtime in the evening and rise time in the morning; more significant phase delays (i.e., difference between current sleep onset and desired bedtime) may require "chronotherapy," which involves delaying bedtime and wake time by 2-3 hr every 24 hr "forward around the clock" until the target bedtime is reached. Because melatonin secretion is highly sensitive to light, exposure to light in the morning (either natural light or a "light box," which typically produces predominantly

blue light) and avoidance of evening light exposure are often beneficial. Exogenous oral melatonin supplementation may also be used; larger mildly sedating doses (i.e., 5 mg) are typically given at bedtime, but some studies have suggested that physiologic doses of oral melatonin (0.3-0.5 mg) administered in the afternoon or early evening (i.e., 5-7 hr before the habitual sleep onset time) seem to be most effective in advancing the sleep phase.

HEALTH SUPERVISION

It is especially important for pediatricians to both screen for and recognize sleep disorders in children and adolescents during health encounters. The well-child visit is an opportunity to educate parents about normal sleep in children and to teach strategies to prevent sleep problems from developing (primary prevention) or from becoming chronic, if problems already exist (secondary prevention). Developmentally appropriate screening for sleep disturbances should take place in the context of every well child visit and should include a range of potential sleep problems; one Table 19-7 outlines a simple sleep screening algorithm, the "BEARS." Because parents may not always be aware of sleep problems, especially in older children and adolescents, it is also important to question the child directly about sleep concerns. The recognition and evaluation of sleep problems in children requires both an understanding of the association between sleep disturbances and daytime consequences, such as irritability, inattention, and poor impulse control, and familiarity with the developmentally appropriate differential diagnoses of common presenting sleep complaints (difficulty initiating and maintaining sleep, episodic nocturnal events). In particular, an assessment of sleep patterns and possible sleep problems should be part of the initial evaluation of every child presenting with behavioral and/or academic problems, especially ADHD.

Effective preventive measures include educating parents of newborns about normal sleep amounts and patterns. The ability to regulate sleep, or control internal states of arousal to fall asleep at bedtime and to fall back asleep during the night, begins to develop in the 1st 8-12 wk of life. Thus, it is important to recommend that parents put their 2-4 mo old infants to bed "drowsy but awake" if they wish to avoid dependence on parental presence at sleep onset and foster the infants' ability to self-soothe. Other important sleep issues include discussing the importance of regular bedtimes, bedtime routines, and transitional objects for toddlers, and providing parents and children with basic information about healthy sleep practices, recommended sleep amounts at different ages, and education regarding signs that a child is not getting sufficient sleep (i.e., wakes with difficulty in the morning, sleeps longer when allowed on weekends and vacation days).

The cultural and family context within which sleep problems in children occur should be considered; for example, cosleeping of infants and parents is a common and accepted practice in many racial/ethnic groups and the goal of independent self-soothing in young infants may not be shared by these families. Anticipatory guidance needs to balance cultural awareness with the critical importance of "safe sleep" conditions in sudden infant death syndrome prevention (i.e., sleeping in the supine position, avoidance of bed-sharing but encouragement of room-sharing in the 1st yr of life) (see Chapter 375). On the other hand, the institution of cosleeping by parents as an attempt to address a child's underlying sleep problem (so-called reactive cosleeping), rather than as a conscious family decision, is likely to yield only a temporary respite from the problem and may set the stage for more significant sleep issues.

EVALUATION OF PEDIATRIC SLEEP PROBLEMS

The clinical evaluation of a child presenting with a sleep problem involves obtaining a careful medical history to assess for potential medical causes of sleep disturbances, such as allergies, concomitant medications, and acute or chronic pain conditions. A developmental history is important because of the aforementioned increased risk of sleep problems in children with neurodevelopmental disorders.

Table 19-7 BEARS Sleep Screening Algorithm

The BEARS instrument is divided into 5 major sleep domains, providing a comprehensive screen for the major sleep disorders affecting children 2-18 yr old. Each sleep domain has a set of age-appropriate "trigger questions" for use in the clinical interview.
B = Bedtime problems
E = Excessive daytime sleepiness
A = Awakenings during the night
R = Regularity and duration of sleep
S = Snoring

Examples of Developmentally Appropriate Trigger Questions			
	TODDLER/PRESCHOOL CHILD (2-5 YR)	**SCHOOL-AGED CHILD (6-12 YR)**	**ADOLESCENT (13-18 YR)**
1. Bedtime problems	Does your child have any problems going to bed? Falling asleep?	Does your child have any problems at bedtime? (P) Do you any problems going to bed? (C)	Do you have any problems falling asleep at bedtime? (C)
2. Excessive daytime sleepiness	Does your child seem overtired or sleepy a lot during the day? Does your child still take naps?	Does your child have difficulty waking in the morning, seem sleepy during the day, or take naps? (P) Do you feel tired a lot? (C)	Do you feel sleepy a lot during the day? In school? While driving? (C)
3. Awakenings during the night	Does your child wake up a lot at night?	Does your child seem to wake up a lot at night? Any sleepwalking or nightmares? (P) Do you wake up a lot at night? Do you have trouble getting back to sleep? (C)	Do you wake up a lot at night? Do you have trouble getting back to sleep? (C)
4. Regularity and duration of sleep	Does your child have a regular bedtime and wake time? What are they?	What time does your child go to bed and get up on school days? Weekends? Do you think your child is getting enough sleep? (P)	What time do you usually go to bed on school nights? Weekends? How much sleep do you usually get? (C)
5. Snoring	Does your child snore a lot or have difficulty breathing at night?	Does your child have loud or nightly snoring or any breathing difficulties at night? (P)	Does your teenager snore loudly or nightly? (P)

C, child; P, parent.

Assessment of the child's current level of functioning (school, home) is a key part of evaluating possible mood, behavioral, and neurocognitive sequelae of sleep problems. Current sleep patterns, including the usual sleep duration and sleep–wake schedule, are often best assessed with a sleep diary, in which a parent (or adolescent) records daily sleep behaviors for an extended period (1-2 wk). A review of sleep habits, such as bedtime routines, daily caffeine intake, and the sleeping environment (e.g., temperature, noise level) may reveal environmental factors that contribute to the sleep problems. Nocturnal symptoms that may be indicative of a medically based sleep disorder, such as OSA (loud snoring, choking or gasping, sweating) or PLMs (restless sleep, repetitive kicking movements), should be elicited. An overnight sleep study is not routinely warranted in the evaluation of a child with sleep problems unless there are symptoms suggestive of OSA or periodic leg movements, unusual features of episodic nocturnal events, or daytime sleepiness that is unexplained.

Behavioral and Psychiatric Disorders

PART III

Chapter 20

Assessment and Interviewing

Heather J. Walter and David R. DeMaso

It is estimated that 13-20% of children living in the United States experience a mental illness in a given year, at a cost of nearly $300 billion. In children, mental illness is more prevalent than leukemia, diabetes, and AIDS combined; more money is spent on mental disorders than on any other childhood illness, including asthma, trauma, upper respiratory infections, and infectious diseases. Although nearly 1 in 5 youths suffers from a psychiatric disorder, 75-80% do not receive needed mental health services. Those who do, primarily receive services in nonspecialty sectors (primary care, schools, child welfare, juvenile justice) where mental health expertise may be limited. Untreated or inadequately treated psychiatric disorders are associated with significant adverse sequelae, including increased morbidity and mortality, failure to achieve mastery in life's developmental tasks (education, occupation, marriage, child-rearing), cross-generational transmission of disadvantage, and substantial costs to society. Psychiatric disorders negatively affect the course of physical illness, adherence to treatment regimens, and use of medical resources. The strong continuity into adulthood of child psychiatric disorders further underscores the importance of early identification and treatment.

AIMS OF ASSESSMENT

A psychosocial assessment in the pediatric setting should determine whether there are signs and symptoms of cognitive, developmental, emotional, behavioral, or social difficulties and characterize these signs and symptoms sufficiently to determine their appropriate management. The focus of the assessment varies with the nature of the presenting problem and the clinical setting. Under emergency circumstances, the focus may be limited to an assessment of dangerousness to self or others for the purpose of determining the safest level of care. In routine circumstances (well-child visits), the focus may be broader, involving a screen for symptoms and functional impairment in all major psychosocial domains. The challenge for the pediatric practitioner will be to determine as accurately as possible whether the presenting signs and symptoms are likely to meet criteria for a psychiatric disorder and whether the severity and complexity of the disorder suggests referral to a mental health specialist or management in the pediatric setting.

PRESENTING PROBLEMS

Infants are presented for clinical attention because of problems with eating and/or sleep regulation, concerns about failure to gain weight and length, poor social responsiveness, limited vocalization, apathy or disinterest, and response to strangers that is excessively fearful or overly familiar. Psychiatric disorders most commonly diagnosed during this period are rumination and reactive attachment disorders.

Toddlers are assessed for concerns about sleep problems, language delay, motor hyperactivity, extreme misbehavior, extreme shyness, inflexible adherence to routine, difficulty separating from parents, struggles over toilet training, dietary issues, and testing limits. Developmental delays and more subtle physiologic, sensory, and motor processing problems can be presented as concerns. Problems with goodness of fit between the child's temperament and the parents' expectations can create relationship difficulties that also require assessment. Psychiatric disorders most commonly diagnosed during this period are autism spectrum and reactive attachment disorders.

Presenting problems in *preschoolers* include elimination difficulties, sibling jealousy, lack of friends, self-destructive impulsiveness, multiple fears, nightmares, refusal to follow directions, somatization, speech that is difficult to understand, and temper tantrums. Psychiatric disorders most commonly diagnosed in this period are autism spectrum, communication, disruptive, attention-deficit/hyperactivity, anxiety (separation, selective mutism), reactive attachment, gender dysphoria, and sleep disorders.

Older children are brought to clinical attention because of concerns about angry or sad mood, bedwetting, overactivity, impulsiveness, distractibility, learning problems, arguing, defiance, nightmares, school refusal, bullying or being bullied, worries and fears, somatization, communication problems, tics, and withdrawal or isolation. Psychiatric disorders most commonly diagnosed during this period are attention-deficit/hyperactivity, disruptive, anxiety (generalized, phobias), elimination, somatic symptom, specific learning, and tic disorders.

Adolescents are assessed for concerns about the family situation, experimentation with sexuality and drugs, delinquency and gang involvement, friendship patterns, issues of independence, identity formation, self-esteem, and morality. Psychiatric disorders most commonly diagnosed during this period are anxiety (panic, social anxiety), depressive, bipolar, psychotic, obsessive-compulsive, impulse control, conduct, substance-related, and eating disorders.

GENERAL PRINCIPLES OF THE PSYCHOSOCIAL INTERVIEW

Psychosocial interviewing in the context of a routine pediatric visit requires adequate time and privacy. The purpose of this line of inquiry should be explained to the child and parents ("to make sure things are going OK at home, at school, and with friends"), along with the limits of confidentiality. Thereafter, the first goal of the interview is to build rapport with both the child and the parents.

With the parents, this rapport is grounded in respect for the parents' knowledge of their child, their role as the central influence in their child's life, and their desire to make a better life for their child. Parents often feel anxious or guilty because they believe that problems in a child imply that their parenting skills are inadequate. Parents' experiences of their own childhood influence the meaning a parent places on a child's feelings and behavior. A good working alliance allows mutual discovery of the past as it is active in the present and permits potential distortions to be modified more readily. Developmentally appropriate overtures can facilitate rapport with the child. Examples include playing peek-a-boo with an infant, racing toy cars with a preschooler, commenting on sports with a child who is wearing a baseball cap, and discussing music with a teenager who is wearing a rock music t-shirt.

After an overture with the child, it is helpful to begin with family-centered interviewing, in which the parent is invited to present any psychosocial concerns (development, thinking, feelings, behavior, peer relationships) about the child. With adolescent patients, it is important to conduct a separate interview to give the adolescent an opportunity to confirm or refute the parent's presentation and to present the problem from his or her perspective. Following the family's undirected presentation of the primary problem, it is important to shift to direct questioning to clarify the duration, frequency, and severity of symptoms, associated distress or functional impairment, and the developmental and environmental context in which the symptoms occur.

Because of the high degree of comorbidity of psychosocial problems in children, after eliciting the presenting problem, the pediatric practitioner should then briefly screen for problems in all of the major

Table 20-1	Mental Health Action Signs

- Feeling very sad or withdrawn for more than 2 weeks
- Seriously trying to harm or kill yourself, or making plans to do so
- Sudden overwhelming fear for no reason, sometimes with a racing heart or fast breathing
- Involvement in many fights, using a weapon, or wanting to badly hurt others
- Severe out-of-control behavior that can hurt yourself or others
- Not eating, throwing up, or using laxatives to make yourself lose weight
- Intense worries or fears that get in the way of your daily activities
- Extreme difficulty in concentrating or staying still that puts you in physical danger or causes school failure
- Repeated use of drugs or alcohol
- Severe mood swings that cause problems in relationships
- Drastic changes in your behavior or personality

From The Action Signs Project, Center for the Advancement of Children's Mental Health at Columbia University.

developmentally appropriate categories of cognitive, developmental, emotional, behavioral, and social disturbance, including problems with mood, anxiety, attention, behavior, thinking and perception, substance use, social relatedness, eating, elimination, development, language, and learning. This can be preceded by a transition statement such as, "Now I'd like to ask about some other issues that I ask all parents and kids about."

A useful guide for this area of inquiry is provided by the "11 Action Signs" (Table 20-1), which was designed to give frontline clinicians the tools needed to recognize early symptoms of mental disorders. Functional impairment can be assessed by inquiring about symptoms and function in the major life domains, including home and family, school, peers, and community. These domains are included in the HEADSS (home, education, activities, drugs, sexuality, suicide/depression) interview guide, often used in the screening of adolescents (Table 20-2).

The nature and severity of the presenting problem(s) can be further characterized through the use of a standardized self-, parent-, or teacher-informant rating scale (Table 20-3 lists some of the scales in the public domain). A rating scale is a type of measure that provides a relatively rapid assessment of a specific construct with an easily derived numerical score that is readily interpreted. The use of rating scales can ensure systematic coverage of relevant symptoms, quantify symptom severity, and document a baseline against which treatment effects can be measured.

Clinical experience and methodologic studies suggest that parents and teachers are more likely than the child to report externalizing problems (disruptive, impulsive, overactive, or antisocial behavior). Children may be more likely to report anxious or depressive feelings, including suicidal thoughts and acts, of which the parents may be unaware. Functional impairment also can be assessed with self and other rating scales. Although concerns have been raised about children's competence as self-reporters (because of limitations in linguistic skills; self-reflection; emotional awareness; ability to monitor behavior, thoughts, and feelings; and tendency toward social desirability), children and adolescents can be reliable and valid self-reporters.

Clinicians are encouraged to become familiar with the psychometric characteristics and appropriate use of at least 1 broad-based measure of psychosocial problems, such as the *Strengths and Difficulties Questionnaire* (SDQ) (http://www.sdqinfo.org/py/sdqinfo/b0.py), the *Pediatric Symptom Checklist* (PSC) (http://www.brightfutures.org/mentalhealth/pdf/professionals/ped_sympton_chklst.pdf), or the *Swanson, Nolan, and Pelham–IV* (SNAP-IV) (http://psychiatryassociatespc.com/doc/SNAP-IV_Parent&Teacher.pdf). These measures are available in multiple languages. If the interview or broad-based rating scale suggests difficulties in one or more specific symptom areas, the clinician can follow with a psychometrically sound, appropriate narrow-band instrument such as the *Vanderbilt ADHD Diagnostic Rating Scale* for attention, behavior, and learning problems, the *Center for Epidemiological Studies Depression Scale for Children* (CES-DC) or *Mood and Feelings Questionnaire* (MFQ) for depression, or the *Screen for Child Anxiety Related Emotional Disorders* (SCARED) for anxiety.

Table 20-2	HEADSS Screening Interview for Taking a Rapid Psychosocial History

PARENT INTERVIEW

Home
- How well does the family get along with each other?

Education
- How well does your child do in school?

Activities
- What does your child like to do?
- Does your child do anything that has you really concerned?
- How does your child get along with peers?

Drugs
- Has your child used drugs or alcohol?

Sexuality
- Are there any issues regarding sexuality or sexual activity that are of concern to you?

Suicide/depression
- Has your child ever been treated for an emotional problem?
- Has your child ever intentionally tried to hurt him-/herself or made threats to others?

ADOLESCENT INTERVIEW

Home
- How do you get along with your parents?

Education
- How do you like school and your teachers?
- How well do you do in school?

Activities
- Do you have a best friend or group of good friends?
- What do you like to do?

Drugs
- Have you used drugs or alcohol?

Sexuality
- Are there any issues regarding sexuality or sexual activity that are of concern to you?

Suicide/depression
- Everyone feels sad or angry some of the time. How about you?
- Did you ever feel so upset that you wished you were not alive or so angry you wanted to hurt someone else badly?

HEADSS, home, education, activities, drugs, sexuality, suicide/depression.
From Cohen E, MacKenzie RG, Yates GL: HEADSS, a psychosocial risk assessment instrument: implications for designing effective intervention programs for runaway youth, J Adolesc Health *12:539–544, 1991.*

Children and adolescents scoring above standardized cutpoints in most cases should be referred to a qualified mental health professional for assessment and treatment, because scores in this range are highly correlated with clinically significant psychiatric disorders. Youths scoring just below or slightly above cutpoints (e.g., subsyndromal or mild mood, anxiety, or disruptive behavior disorders) may be appropriate for management in the pediatric setting, as may youths scoring well above cutpoints for certain neurodevelopmental disorders (attention-deficit/hyperactivity, autism spectrum, tic).

The safety of the child in the context of the home and community is of paramount importance. The interview should sensitively assess whether the child has been exposed to any frightening events, including abuse, neglect, bullying, marital discord, or domestic or community violence; whether the child shows any indication of dangerousness to self or others or a severely altered mental status (psychosis, intoxication, rage, hopelessness); or whether the child (if age-appropriate) has been involved in any risky behavior, including running away, staying out without permission, truancy, gang involvement, experimentation with substances, and unprotected sexuality. The interview also should assess the capacity of the parents to adequately provide for the child's

Table 20-3 Select List of Mental Health Rating Scales in the Public Domain

physical, emotional, and social needs or whether parental capacity has been diminished by psychiatric disorder, family dysfunction, or the sequelae of disadvantaged socioeconomic status. Any indications of threats to the child's safety should be immediately followed by thorough assessment and protective action.

INDICATIONS FOR REFERRAL

There is variability in the level of confidence pediatric practitioners perceive in diagnosing psychosocial problems in children and adolescents. Pediatric practitioners who have familiarity with psychiatric diagnostic criteria may feel confident diagnosing certain disorders, particularly the neurodevelopmental and other biologically based disorders (attention-deficit/hyperactivity, autism spectrum, and tic disorders, enuresis, encopresis, insomnia, anorexia). The disorders about which pediatric practitioners might have less diagnostic confidence include the disruptive/impulse control/conduct, depressive, bipolar, anxiety, psychotic, obsessive-compulsive, trauma-related, somatic symptom, and substance-related disorders. Pediatric practitioners should refer to a qualified mental health practitioner whenever they experience diagnostic uncertainty with a child who has distressing or functionally impairing psychosocial symptoms. Children who upon initial assessment are found to have indicators of dangerousness always should be immediately referred to a qualified mental health professional.

PSYCHIATRIC DIAGNOSTIC EVALUATION

The objectives of the psychiatric diagnostic evaluation of the child and adolescent are to determine whether psychopathology or developmental risk is present and if so, to establish an explanatory formulation and a differential diagnosis, and to determine whether treatment is indicated and if so, to develop a treatment plan and facilitate the parents' and child's involvement in the plan. The aims of the diagnostic evaluation are to clarify the reasons for the referral; to obtain an accurate accounting of the child's developmental functioning and the nature and extent of the child's psychosocial difficulties, functional impairment, and subjective distress; and to identify potential individual, family, or environmental factors that might account for, influence, or ameliorate these difficulties. The issues relevant to diagnosis and treatment planning can span genetic, constitutional, and temperamental factors; individual psychodynamics; cognitive, language, and social skills; family patterns of interaction and child- rearing practices; and community, school, and socioeconomic influences.

The focus of the evaluation is developmental; it seeks to describe the child's functioning in various realms and to assess the child's adaptation in these areas relative to that expected for the child's age and phase of development. The developmental perspective extends beyond current difficulties to vulnerabilities that can affect future development and as such are important targets for preventive intervention. Vulnerabilities may include subthreshold or subsyndromal difficulties that, especially when manifold, often are accompanied by significant distress or impairment and as such are important as potential harbingers of future problems.

Throughout the assessment, the clinician focuses on identifying a realistic balance of vulnerabilities and strengths in the child, in the parents, and in the parent–child interactions. From this strength-based approach, over time a hopeful family narrative is co-constructed to frame the child's current developmental progress and predict the child's ongoing progress within the scope of current risk and protective factors.

Although the scope of the evaluation will vary with the clinical circumstance, the full *psychiatric diagnostic evaluation* has 12 major components: the presenting problem(s) and the context in which they occur; a review of psychiatric symptoms; a risk assessment; a history of psychiatric treatment; a medical history, a developmental history; an educational history; a family history; a mental status examination; a biopsychosocial clinical formulation; a *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) diagnosis; and a treatment plan. For infants and young children, the presenting problem and historical information is derived from parents and other informants. As children mature, they become increasingly important contributors to the information base, and they become the primary source of information in later adolescence. Information relevant to formulation and differential diagnosis is derived in multiple ways, including directive and nondirective questioning, interactive play, and observation of the child alone and together with the caregiver(s).

The *explication of the presenting problem(s)* includes information about onset, duration, frequency, and severity of symptoms, associated

distress and/or functional impairment, and predisposing, precipitating, perpetuating, and ameliorating contextual factors. The *symptom review* assesses potential comorbidity in the major domains of child and adolescent psychopathology, including problems with intellectual, communication, motor, learning, and developmental capabilities; attention deficits; angry, sad, or elated mood; anxiety; obsessions or compulsions; trauma or stress reactions; somatic symptoms; eating, elimination, sleep, or gender disturbances; disruptive, impulse-control, or conduct problems; psychosis; or substance abuse or addiction. The *risk assessment* includes a careful assessment of risk status, including suicidality, homicidality, assaultiveness, self-injuriousness, and involvement in risky behavior or situations. The *history of psychiatric treatment* includes gathering information about prior emergency mental health assessments, psychiatric hospitalizations, day treatment, psychotherapy, pharmacotherapy, and nontraditional treatments.

The *medical history* includes information about the source of primary care, the frequency of health supervision, past and current medical illnesses and treatments, and the youth and family's history of adherence to medical treatment. A systematic review of organ or functional systems facilitates the identification of abnormalities that require investigation or monitoring by the pediatric practitioner, as well as the identification of cautionary factors related to the prescription of psychotropic medication. The *developmental history* includes information about the circumstances of conception, pregnancy, or adoption; pre-, peri-, or postnatal insults; attachment and temperament; cognitive, motor, linguistic, emotional, social, and moral development; health habits, sexuality, and substance use (as age-appropriate), coping and defensive structure, future orientation, and perceived strengths. The *educational history* includes schools attended; typical grades, attendance, and behavior; special education services; disciplinary actions; social relationships; extracurricular activities; and barriers to learning. The *family history* assesses family composition; sociodemographic and neighborhood characteristics; domiciliary arrangements; parenting capacities; family function; medical and psychiatric histories of family members; and cultural/religious affiliations. The *mental status examination* assesses appearance, relatedness, cognition, communication, mood, affective expression, behavior, memory, orientation, and perception.

The evaluation culminates in a *biopsychosocial formulation and diagnosis*. The *biopsychosocial formulation* is derived from an assessment of vulnerabilities and strengths in the biologic, psychologic, and social domains and serves to identify targets for intervention and treatment. In the biologic domain, major vulnerabilities include a family history of psychiatric disorder and personality or behavior problems, and a personal history of pre-, peri-, or postnatal insults; cognitive or linguistic impairments; physical illness; and a difficult temperament. In the psychological domain, major vulnerabilities include failure to achieve developmental tasks and maladaptive coping and defensive styles. In the social domain, major vulnerabilities include parental incapacity; unskilled parenting; family dysfunction; social isolation; unfavorable school setting; unsupportive community structures; and sociodemographic disadvantage. Major strengths include cognitive and linguistic capability; physical health and attractiveness; stable, moderate temperamental characteristics; and stable and supportive parenting, family, peer, and community structures. The biopsychosocial formulation can be organized to reflect predisposing, precipitating, perpetuating, and protective (ameliorating) factors (the "4 Ps") influencing the development of the observed psychopathology.

The *diagnosis* must be made in accordance with the nomenclature in the DSM-5. This nomenclature categorizes cross-sectional phenomenology into discrete clinical syndromes and seeks to improve diagnostic accuracy at the expense of theories of causation and dimensional presentations. By DSM-5 convention, if diagnostic criteria are met, the diagnosis is given (except where hierarchical rules apply); consequently psychiatric comorbidity is a common occurrence.

The psychiatric diagnostic evaluation culminates in a *treatment plan* that brings the broad array of targeted psychosocial interventions to the service of the child. Diagnoses drive the choice of evidence-based psychotherapeutic and psychopharmacologic treatments. The formulation drives the selection of interventions targeted at biologic, psychologic, and social vulnerabilities and strengths. Many of these treatments and interventions are described in the succeeding chapters.

SPECIAL CONSIDERATIONS IN THE DIAGNOSTIC EVALUATION OF INFANTS AND YOUNG CHILDREN

Psychiatric evaluation of infants and young children includes the domains of physiology, temperament, motor behavior, affective behavior, social behavior, and communication. Although much of the information in these domains will be derived from parent report, much also can be gleaned from nonverbal behavior and observation of the parent-child interaction. Observations should include predominant affective tone of parent and child (positive, negative, apathetic); involvement in the situation (curiosity, disinterest); social responsiveness (mutuality of gaze, auditory responsiveness); and reactions to transitions (including separation).

A screen for maternal depression (see http://www.medicalhomeportal.org/clinical-practice/screening-and-prevention/maternal-depression for several examples) is critical at this stage, as is an assessment of the mother's (or other caregiver's) ability to rapidly respond on a contingent basis to the child's expressed needs, regulate the child's rapid shifts of emotion and behavior, and provide a stimulus shelter to prevent the child from being overwhelmed.

Standardized screening instruments *(Bayley Scales of Infant Development)* designed for this age group can be helpful in systematizing the evaluation. In addition, the *Infant, Toddler and Preschool Mental Status Exam* (ITP-MSE) is a reference tool that describes how traditional categories of the mental status exam can be adapted to observations of young children. Additional categories, including sensory and state regulation, have been added that reflect important areas of development in young children.

Diagnostic systems that are more age-appropriate than DSM-5 have been developed for infants and young children. These systems include the *Research Diagnostic Criteria—Preschool Age* (RDC-PA) and the *Zero to Three Diagnostic Classification of Mental Health and Developmental Disorders of Infancy and Early Childhood-Revised* (DC: 0-3R). The DC: 0-3R includes relationship classification that assesses the range of interactional adaptation in each parent–child relationship and regulation disorders of sensory processing that identify a range of constitutionally and maturationally based sensory reactivity patterns, motor patterns, and behavior patterns that together can dysregulate a child internally and the child's interactions with caregivers.

Chapter 21

Psychological Treatment of Children and Adolescents

David R. DeMaso and Heather J. Walter

Three-quarters of children with mental health problems are seen in primary care. About half of the treatment for psychiatric disorders is provided in primary care settings and most psychotropic prescriptions for youth are written by primary care practitioners. Barriers that prevent children and their families from obtaining needed mental health services include stigma, shortages of mental health

professionals, inadequate coverage of mental health services in public and private health insurance programs, inadequately trained clinicians, inadequate time for primary care providers to identify mental health issues, and fragmented service delivery systems.

The provision of supportive counseling, anticipatory guidance, and parent psychoeducation about mental health problems combined with medication management of neurodevelopmental (attention-deficit/hyperactivity [ADHD], autism spectrum, tic), sleep, and elimination disorders are commonly undertaken by the pediatric practitioner. Youth with other psychiatric disorders (psychotic, bipolar, depressive, anxiety, obsessive-compulsive, trauma-related, somatic symptom, dissociative, gender dysphoric, disruptive/impulse-control/conduct, and substance-related) require initial evaluation, treatment planning, and stabilization by child-trained mental health clinicians. However, the pediatric practitioner often resumes the care of these youth once stabilized.

Barriers to providing mental health services in the primary care setting include lack of mental health training for staff, insufficient time, lack of knowledge about community mental healthcare resources, and inadequate reimbursement. In the face of these challenges, safe and effective mental healthcare of children and adolescents requires effective collaboration between pediatric and mental health practitioners. Several models of effective collaboration in the primary care setting have been advanced; most converge in recommending the following components: (1) screening for and early detection of mental health problems; (2) triage/referral to appropriate mental health treatment; (3) timely access to mental health consultation and direct mental health assessment (in-person or via telepsychiatry); (4) care coordination (by a designated care coordinator in the primary care setting); (5) access to specialty mental health treatment services; and (6) education of primary care practitioners around the accurate assessment and safe and effective treatment of child and adolescent psychiatric disorders.

Bibliography is available at Expert Consult.

Table 21-1 Best Principles for Use of Psychotropic Medications

1. Before initiating pharmacotherapy, a psychiatric evaluation is completed.
2. Before initiating pharmacotherapy, a medical history is obtained and a medical evaluation is considered when appropriate.
3. The prescriber communicates with other professionals to obtain collateral history and collaborate in the monitoring of outcome and side effects during the medication trial.
4. The prescriber develops a psychosocial and psychopharmacological treatment plan based upon the best available evidence.
5. The prescriber develops a plan to monitor the patient during the medication trial.
6. The prescriber is cautious when the medication trial cannot be appropriately monitored.
7. The prescriber educates the patient and family about the patient's diagnosis and treatment plan.
8. The prescriber obtains and documents informed consent before initiating the medication trial and at appropriate intervals during the trial.
9. The informed consent process focuses on the risks and benefits of the proposed and alternative treatments.
10. The medication trial should involve an adequate dose of medication for an adequate duration.
11. The prescriber reassesses the patient if the patient fails to respond to the medication trial as expected.
12. The prescriber has a clear rationale for using medication combinations.
13. The prescriber has a specific plan for medication discontinuation.

Modified from American Academy of Child and Adolescent Psychiatry: Practice parameter on the use of psychotropic medication in children and adolescents. J Am Acad Child Adolesc Psychiatry *48(9):961–973, 2009.*

21.1 Psychopharmacology

David R. DeMaso and Heather J. Walter

Data are available regarding the safety and efficacy for the use of *single* psychotropic medications for the treatment of a number of childhood psychiatric disorders, including depressive, obsessive-compulsive, ADHD, anxiety, bipolar, psychotic, and tic disorders. Evidence also supports the use of psychotropic medications for agitation, aggression and serious problems with impulse control in disruptive/impulse-control/conduct and autism spectrum disorders.

The evidence for using multiple psychotropic medications at the same time is much smaller. Combinations of medications are used to address complex comorbid conditions, manage side effects, increase treatment response, and/or address symptoms hypothesized to be associated with multiple underlying neurotransmitter abnormalities (dopamine agonists for hyperactivity and serotonin agonists for anxiety).

To ensure safe and appropriate use of psychotropic medications, prescribers should follow best practice principles that underlie medication prescribing (Table 21-1). The use of medication involves a series of interconnected steps, including performing an assessment, deciding on treatment and a monitoring plan, obtaining treatment assent and/or consent, and implementing treatment. Cognitive, emotional, and/or behavior symptoms are targets for medication intervention when there is no response to available evidence-based psychosocial interventions, there is a significant risk of harm, and/or there is significant distress or functional impairment. Commonly encountered target symptom domains include agitation, aggression, anxiety, depression, hyperactivity, inattention, impulsivity, mania, and psychosis (Table 21-2).

Table 21-2 Target Symptom Approach to Psychopharmacologic Management

TARGET SYMPTOM	MEDICATION CONSIDERATIONS
Agitation	Atypical antipsychotic Typical antipsychotic Anxiolytic (e.g., benzodiazepine)
Aggression	Stimulant Atypical antipsychotic
Anxiety	Antidepressant Anxiolytic
Depression	Antidepressant
Hyperactivity, inattention, impulsivity	Stimulant Atomoxetine Alpha-agonist
Mania	Atypical antipsychotic
Psychosis	Atypical antipsychotic

Modified from Shaw RJ, DeMaso DR: Clinical manual of pediatric psychosomatic medicine: mental health consultation with physically ill children and adolescents, *Washington, DC, 2006, American Psychiatric Press, p. 306.*

STIMULANTS AND OTHER ADHD MEDICATIONS

Stimulants are sympathomimetic drugs that act both in the central nervous system and peripherally by enhancing dopaminergic and noradrenergic transmission (Table 21-3). There is strong evidence for the effectiveness of these medications for the treatment of ADHD (***number needed to treat*** [**NNT**] approximates 4) as well as aggression (NNT approximates 4), and moderate evidence for the treatment of hyperactivity in autism spectrum disorder. In some cases, stimulants are used as an adjunct in the treatment of depression and for fatigue

Amphetamine combination (Adderall XR)	ADHD (6 and up)	Inattention Hyperactivity Impulsivity	6-12: 5-10 mg >12: 10-20 mg	6-12: 30 mg >12: 40 mg
Dextroamphetamine (Dexedrine Spansule)	ADHD (6 and up)	Inattention Hyperactivity Impulsivity	5-40 mg	40 mg
Intermediate Acting Methylphenidate (Metadate CD, Metadate ER, Ritalin LA, Ritalin SR)	ADHD (6 and up)	Inattention Hyperactivity Impulsivity	10-60 mg	60 mg
Short Acting				
Dexmethylphenidate (Focalin)	ADHD (6 and up)	Inattention Hyperactivity Impulsivity	2.5-20 mg	20 mg
Methylphenidate (Ritalin, Methylin)	ADHD (6 and up)	Inattention Hyperactivity Impulsivity	5-30 mg	60 mg
Amphetamine combination (Adderall)	ADHD (3 and up)	Inattention Hyperactivity Impulsivity	3-5: 2.5-40 mg >6: 5-40 mg	40 mg
Dextroamphetamine (Dexedrine)	ADHD (6 and up)	Inattention Hyperactivity Impulsivity	2.5-40 mg	40 mg
SEROTONIN-NOREPINEPHRINE REUPTAKE INHIBITOR Atomoxetine (Strattera)	ADHD (6 and up)	Inattention Hyperactivity Impulsivity	<70 kg: 0.5-1.2 mg/kg >70 kg: 40-80 mg	<70 kg: 1.4 mg/kg >70 kg: 100 mg
α-AGONISTS Clonidine (Catapres)	Not approved for ADHD in children & adolescents	Inattention Hyperactivity Impulsivity	27-40.5 kg: 0.05-0.2 mg 40.5-45 kg: 0.05-0.3 mg >45 kg: 0.05-0.4 mg	27-40.5 kg: 0.2 mg 40.5-45 kg: 0.3 mg >45 kg: 0.4 mg
Clonidine (Kapvay)	ADHD (6-17)	Inattention Hyperactivity Impulsivity	0.1-0.4 mg/day	0.4 mg
Guanfacine (Tenex)	Not approved for ADHD in children & adolescents	Inattention Hyperactivity Impulsivity	27-40.5 kg: 0.5-2 mg 40.5-45 kg: 0.5-3 mg >45 kg: 0.5-4 mg	27-40.5 kg: 2 mg 40.5-45 kg: 3 mg >45 kg: 4 mg
Guanfacine (Intuniv)	ADHD (6-17)	Inattention Hyperactivity Impulsivity	1-4 mg	4 mg

ADHD, attention-deficit/hyperactivity disorder.

or malaise associated with chronic physical illnesses. There is a range of stimulant options, including those with short half-lives (typically 4 hr) and those with long half-lives (8-12 hr). The most commonly reported side effects are appetite suppression and sleep disturbances. Nervousness, headaches, abdominal pain, dizziness, palpitations, tachycardia have also been reported. More serious reactions include psychosis, mania, hypertension, dependency, and abuse. Anorexia and weight loss have been noted with controversy about their impact on ultimate height attainment.

Sudden death has been reported in association with the use of stimulants in children, although a large study did not find an increased rate of serious cardiac events.. Currently, no routine pretreatment cardiology evaluation is indicated unless the patient has a structural cardiac abnormality and/or cardiac-related symptoms; in this situation, cardiology clearance is recommended.

Atomoxetine is a selective inhibitor of presynaptic norepinephrine transporters; it increases dopamine and norepinephrine in the prefrontal cortex. It is effective in treating ADHD for 24 hr despite a plasma half-life of 4 hr. Common side effects include headache, abdominal pain, insomnia, somnolence, erectile dysfunction, irritability, fatigue, weight loss, and dizziness along with nonclinical increases in heart rate and blood pressure. More serious reactions include psychosis, mania, aggressive behavior, suicidal ideation, depression, seizures, and hepatoxicity.

The α-adrenergic agents (clonidine and guanfacine) are presynaptic adrenergic agonists that appear to stimulate inhibitory presynaptic autoreceptors in the central nervous system. These medications (see Table 21-5) have moderate evidence for the treatment of ADHD and ADHD with oppositional defiant disorder, and weak evidence for the treatment of agitation in autism. Two longer-acting preparations of each agent (Kapvay and Intuniv) have recently received FDA approval for use in ADHD. Sedation, hypotension, dry mouth, depression, and confusion are potential side effects. Abrupt withdrawal can result in rebound hypertension. Guanfacine appears to be less sedating and to have a longer duration of action than clonidine.

ANTIDEPRESSANTS

Antidepressant drugs act on pre- and postsynaptic receptors affecting the release and reuptake of brain neurotransmitters, including norepinephrine, serotonin, and dopamine (Table 21-4). There is strong evidence for the effectiveness of antidepressant medications in the treatment of anxiety and obsessive-compulsive disorders (NNT approximates 3 and 6, respectively), and weaker evidence for the treatment of depressive disorders (NNT approximates 10). Suicidal

Table 21-4 Medications for Depression and Anxiety Symptoms

NAME	FDA APPROVED (AGE RANGE IN YEARS)	TARGET SYMPTOMS	USUAL DAILY DOSAGE RANGE	SUGGESTED TOP END OF DAILY DOSAGE
SELECTIVE SEROTONIN REUPTAKE INHIBITORS				
Citalopram (Celexa)	Not approved for anxiety & depression in children & adolescents	Depression Anxiety Obsessions/compulsions	20-40 mg	40 mg
Escitalopram (Lexapro)	Depression (12-17)	Depression Anxiety Obsessions/compulsions	10-20 mg	20 mg
Fluoxetine (Prozac)	Depression (8-17) OCD (7-17)	Depression Anxiety Obsessions/compulsions	10-60 mg	60 mg
Sertraline (Zoloft)	OCD (6-17)	Depression Anxiety Obsessions/compulsions	25-200 mg	200 mg
TRICYCLIC ANTIDEPRESSANTS				
Clomipramine (Anafranil)	OCD (10-17)	Obsessions/compulsions	25-100 mg	Lesser of 200 mg or 3 mg/kg
ATYPICAL ANTIDEPRESSANTS				
Bupropion (Wellbutrin XL)	Not approved for depression in children & adolescents	Depression	150-300 mg	450 mg
Venlafaxine (Effexor XR)	Not approved for anxiety & depression in children & adolescents	Depression Anxiety	75-225 mg	225 mg
ANXIOLYTIC AGENTS				
Lorazepam (Ativan)	Not approved for anxiety	Anxiety	0.5-6 mg	10 mg
Clonazepam (Klonopin)	Not approved for panic in children & adolescents	Panic	0.5-1 mg	4 mg
Buspirone (BuSpar)	Not approved for anxiety & depression in children & adolescents	Anxiety	15-30 mg	60 mg
Hydroxyzine (Atarax, Vistaril)	Anxiety	Anxiety	50 mg >6: 50-100 mg	<6: 2 mg/kg 50 mg >6: 100 mg

ADHD: attention-deficit/hyperactivity disorder; OCD: obsessive-compulsive disorder.

Table 21-5 Medications for Psychosis and Agitation

NAME	FDA APPROVED (AGE RANGE IN YEARS)	TARGET SYMPTOMS	USUAL DAILY DOSAGE RANGE	SUGGESTED TOP END OF DAILY DOSAGE
ATYPICAL ANTIPSYCHOTICS				
Aripiprazole (Abilify)	Bipolar disorder (10-17) Schizophrenia (13-17) Irritability in autism (6-17)	Psychosis Mania Irritability Aggression Agitation	2-30 mg qd	30 mg Autism: 15 mg
Olanzapine (Zyprexa)	Bipolar disorder (13-17) Schizophrenia (13-17)	Psychosis Mania Agitation	2.5-10 mg qd	20 mg
Quetiapine (Seroquel)	Bipolar disorder (10-17) Schizophrenia (13-17)	Psychosis Mania Agitation	Bipolar: 400-600 mg Schizophrenia: 400-800 mg	Bipolar: 600 mg Schizophrenia: 800 mg
Risperidone (Risperdal)	Bipolar disorder (10-17) Schizophrenia (13-17) Irritability in autism (5-17)	Psychosis Mania Aggression Agitation Irritability	0.5-6 mg Autism: 15-20 kg: 0.25 mg-0.5 mg >20 kg: 0.5-1 mg	Bipolar & Schizophrenia: 6 mg Autism: 3 mg
Ziprasidone (Geodon)	Not approved for psychosis, mania, aggression, or agitation in children & adolescents	Psychosis Mania Agitation	40-160 mg	200 mg
TYPICAL ANTIPSYCHOTICS				
Haloperidol (Haldol)	Psychosis (3-17) Tourette (3-17) Severe behavioral disorders (3-17) Agitation (3-17)	Psychosis Mania Aggression Agitation	3-12: 0.05-0.15 mg/kg >12: 0.5-5 mg Agitation: 3-12: 0.01-0.03 mg/kg >12: 0.5-10 mg	3-12: 0.15 mg/kg/day >12: maximum 100 mg for severe refractory cases

thoughts have been reported during treatment with all antidepressant medications. The overall risk difference of suicidal ideation/attempts across all randomized controlled antidepressant trials and indications has been reported to be 0.7%, corresponding to a ***number needed to harm*** of 143.

The ***selective serotonin reuptake inhibitors*** **(SSRIs)**, which, as their name suggests, inhibit the reuptake of serotonin, have a large margin of safety with no appreciable cardiovascular effects. Side effects include irritability, insomnia, appetite changes, gastrointestinal symptoms, headaches, diaphoresis, restlessness, behavioral activation, and sexual dysfunction. Withdrawal symptoms are more common in short-acting SSRIs (sertraline, citalopram, escitalopram), leading to a recommendation for divided doses if these medications are used.

The ***tricyclic antidepressants*** **(TCAs)** have mixed mechanisms of action (e.g., clomipramine is primarily serotonergic; imipramine is both noradrenergic and serotonergic). With the advent of the SSRIs, the lack of efficacy studies (particularly in depression), and more serious side effects, the use of TCAs in children has declined. They continue to be used in the treatment of some anxiety disorders (particularly obsessive-compulsive disorder) and, unlike the SSRIs, can be helpful in pain disorders. They have a narrow therapeutic index, with overdoses being potentially fatal (see Chapter 63). Anticholinergic symptoms (e.g., dry mouth, blurred vision, and constipation) are the most common side effects. TCAs can have cardiac conduction effects in doses higher than 3.5 mg/kg. Blood pressure and electrocardiographic monitoring is indicated at doses above this level.

The **atypical antidepressants** include bupropion and venlafaxine (see Table 21-4); because of their sparse evidence base, they are third-line medications (after fluoxetine and the other SSRIs) for anxiety and depressive disorders. Bupropion has also been used for smoking cessation and ADHD. Bupropion appears to have an indirect mixed agonist effect on dopamine and norepinephrine transmission. Common side effects include irritability, nausea, anorexia, headache, and insomnia. Venlafaxine has both serotonergic and noradrenergic properties. Side effects are similar to SSRIs, including irritability, insomnia, headaches, anorexia, nervousness, dizziness, and blood pressure changes.

Anxiolytic agents (including lorazepam, clonazepam, buspirone, and hydroxyzine) have all been effectively used for acute situational anxiety (see Table 21-4). Their efficacy as chronic medication is poorer, particularly when used as a monotherapy agent.

ANTIPSYCHOTICS

Based on their mechanism of action, antipsychotic medications can be divided into typical (blocking dopamine D_2 receptors) and atypical (mixed dopaminergic and serotoninergic [$5\text{-}HT_2$] activity) agents (Table 21-5).

The **atypical antipsychotics** have relatively strong antagonistic interactions with $5\text{-}HT_2$ receptors and perhaps more variable activity at central adrenergic, cholinergic, and histaminic sites, which might account for varying side effects noted among these agents. These medications have strong evidence for the treatment of agitation in autism (NNT approximates 2-7), and for the treatment of schizophrenia (NNT approximates 4-10), bipolar disorder (NNT approximates 3-4), and aggression (NNT approximates 2-5). Risperidone and aripiprazole are 2 of the most well-studied and commonly used medications in this class.

The atypical antipsychotics have significant side effects including extrapyramidal symptoms (e.g., restlessness and dyskinesias), weight gain, metabolic syndrome, diabetes, hyperlipidemia, hyperprolactinemia, hematologic adverse effects (e.g., leukopenia or neutropenia), seizures, hepatotoxicity, neuroleptic malignant syndrome, and cardiovascular effects. For all atypical antipsychotics, body mass index, blood pressure, fasting blood glucose, fasting lipid profiles, and abnormal movements should be closely monitored. If there is a family or personal history suggestive of cardiac disease, electrocardiograms should also be monitored.

Table 21-6 Medications for Mania

	FDA APPROVED (AGE RANGE IN YEARS)	TARGET SYMPTOMS	USUAL DAILY DOSAGE RANGE	SUGGESTED TOP END OF DAILY DOSAGE
MOOD STABILIZERS				
Lithium carbonate (Eskalith, Eskalith CR, Lithobid)	Bipolar disorder (12-17)	Mania Depression	<22 kg: 600 mg 22-41 kg: 900 mg >41 kg: 1200 mg	1800 mg
Divalproex (Depakote, Depakote ER)	Not approved for mania in children & adolescents	Mania	Teen: 10-60 mg/kg *(Blood valproic acid level 50-100 μg/mL)*	60 mg/kg
ATYPICAL ANTIPSYCHOTICS				
Aripiprazole (Abilify)	Bipolar disorder (10-17) Schizophrenia (13-17) Irritability in autism (6-17)	Irritability Psychosis Mania Aggression Agitation	2-30 mg	30 mg Autism: 15 mg
Risperidone (Risperdal)	Bipolar disorder (10-17) Schizophrenia (13-17) Irritability in autism (5-17)	Psychosis Mania Aggression Agitation Irritability	0.5-6 mg Autism: 15-20 kg: 0.25 mg-0.5 mg >20 kg: 0.5-1 mg	Bipolar & Schizophrenia: 6 mg Autism: 3 mg

Haloperidol is a high-potency butyrophenone that is the typical antipsychotic most commonly used. This medication is useful in psychosis, Tourette disorder, and severe agitation. Side effects include anticholinergic effects, weight gain, drowsiness, and extrapyramidal symptoms (dystonia, rigidity, tremor, and akathisia). There is a risk of tardive dyskinesia (see Chapter 597.3) with chronic administration.

MOOD STABILIZERS

Because of their limited evidence of effectiveness and concerns about safety, mood stabilizer medications (Table 21-6) have limited use in the treatment of child and adolescent psychiatric disorders. For the treatment of bipolar mania in adolescents, atypical antipsychotics are considered first-line therapy.

Lithium's mechanism of action is not well understood; proposed theories relate to neurotransmission, endocrine effects, circadian rhythm, and cellular processes. Common side effects include polyuria and polydipsia and central nervous system symptoms (tremor, somnolence, and memory impairment). Periodic monitoring of lithium levels along with thyroid and renal function is needed. Lithium serum levels of 0.8-1.2 mEq/L are targeted for acute episodes and 0.6-0.9 mEq/L are targeted for maintenance therapy.

Valproic acid is an anticonvulsant with a therapeutic plasma concentration range of 50-100 μg/mL. Common side effects include sedation, gastrointestinal symptoms, and hair thinning. Idiosyncratic bone marrow suppression and liver toxicity have been reported, necessitating monitoring of blood counts as well as liver and kidney function.

MEDICATION USE IN PHYSICAL ILLNESS

There are special considerations in the use of psychotropic medications with physically ill children. Between 80% and 95% of psychotropic medications are protein bound, with the exceptions being lithium (0%), methylphenidate (10-30%), venlafaxine (25-30%), gabapentin (0-3%), and topiramate (9-17%). As a result, psychotropic levels may be directly affected because albumin binding is reduced in many physical illnesses. Metabolism is primarily through the liver and gastrointestinal tract, with excretion via the kidney. Therefore, dosages may need to be adjusted in children with hepatic or renal impairment.

Hepatic Disease

Lower doses of medications may be required in in patients with hepatic disease. Initial dosing of medications should be reduced and titration should proceed slowly. In steady-state situations, changes in protein binding can result in elevated unbound medication, resulting in increased drug action even in the presence of normal serum drug concentrations. Because it is often difficult to predict changes in protein binding, it is important to maintain attention to the clinical effects of psychotropic medications and not rely exclusively on serum drug concentrations.

In acute hepatitis, there is generally no need to modify dosing because metabolism is only minimally altered. In chronic hepatitis and cirrhosis, hepatocytes are destroyed and doses may need to be modified.

Medications with high baseline rates of liver clearance (e.g., haloperidol, sertraline, venlafaxine, TCAs) are significantly affected by hepatic disease. For drugs that have significant hepatic metabolism, intravenous administration may be preferred because parenteral administration avoids first-pass liver metabolic effects and the dosing and action of parenteral medications are similar to those in patients with normal hepatic function. Valproic acid can impair the metabolism of the hepatocyte disproportionate to the degree of hepatocellular damage. In patients with valproate-induced liver injury, low albumin, high prothrombin, and high ammonia may be seen without significant elevation in liver transaminases.

Gastrointestinal Disease

Medications with anticholinergic side effects can slow gastrointestinal motility, affecting absorption and causing constipation. SSRIs increase gastric motility and can cause diarrhea. SSRIs have the potential to increase the risk of gastrointestinal bleeding, especially when they are co-administered with nonsteroidal anti-inflammatory drugs. Extended-release or controlled-release preparations of medications can reduce gastrointestinal side effects, particularly where gastric distress is related to rapid increases in plasma drug concentrations.

Kidney Disease

With the exceptions of lithium and gabapentin, psychotropic medications do not generally require significant dosing adjustments in kidney failure. It is important to monitor serum concentrations in renal insufficiency, particularly for medications with a narrow therapeutic index; cyclosporine can elevate serum lithium levels by decreasing lithium excretion. Patients with kidney failure and those on dialysis appear to be more sensitive to TCA side effects, possibly because of the accumulation of hydroxylated tricyclic metabolites.

Because most psychotropic medications are highly protein-bound, they are not significantly cleared by dialysis. Lithium, gabapentin, and topiramate are essentially completely removed by dialysis, and the common practice is to administer these medications after dialysis. Patients on dialysis often have significant fluid shifts and are at risk for dehydration, with neuroleptic malignant syndrome being more likely in these situations.

Heart Disease

Cardiovascular effects of psychotropic medications can include orthostatic hypotension, conduction disturbances, and arrhythmias. Orthostatic hypotension is one of the most common cardiovascular side effects of TCAs. Trazodone can cause orthostatic hypotension and exacerbate myocardial instability; SSRIs and bupropion are preferred as antidepressant agents in patients with heart disease.

There is the potential for increased morbidity and mortality in patients with preexisting cardiac conduction problems. Some of the calcium channel-blocking agents (e.g., verapamil) can slow atrioventricular conduction and can theoretically interact with a TCA. Patients with Wolff-Parkinson-White syndrome (see Chapter 435.3) who have a short PR interval (<0.12 sec) and widened QRS interval associated with paroxysmal tachycardia are at high risk for life-threatening ventricular tachycardia that may be exacerbated by the use of a TCA. Quinidine-like effects of TCAs and the antipsychotic agents can lead to prolongation of the QTc interval, with increased risk of ventricular tachycardia and ventricular fibrillation, particularly in patients with structural heart disease. Patients with a baseline QTc interval of >440 msec should be considered at particular risk. The range of normal QTc values in children is 400 msec ± 25-30 msec. A QTc value that exceeds 2 SD (>450-460 msec) is considered too long and may be associated with increased mortality. An increase in the QTc from baseline of >60 msec is also associated with increased mortality.

Respiratory Disease

Anxiolytic agents can increase the risk of respiratory suppression in patients with pulmonary disease. SSRIs and buspirone are good alternative medications for treating anxiety. Consideration should be given to possible airway compromise due to acute laryngospasm when dopamine-blocking agents such as antipsychotic or antiemetic medications are used.

Neurologic Disease

Psychotropic medications can be used safely with epilepsy following consideration of potential interactions between the psychotropic medication, the seizure disorder, and the anticonvulsant medication. Any behavioral toxicity of anticonvulsants used either alone or in combination should be considered before proceeding with psychotropic treatment. Simplification of combination anticonvulsant therapy or a change to another agent can result in a reduction of behavioral or emotional symptoms and obviate the need for psychotropic intervention. Clomipramine and bupropion possess significant seizure-inducing properties and should be avoided when the risk of seizures is present.

Neuroleptic Malignant Syndrome

Neuroleptic malignant syndrome is a rare and potentially fatal reaction that can occur during treatment with antipsychotic agents (see Chapter 176). The syndrome generally manifests with fever, muscle rigidity, autonomic instability, and delirium. It is associated with elevated serum creatine phosphokinase levels, a metabolic acidosis, and high end-tidal CO_2 excretion. It has been estimated to occur in 0.2-1% of patients treated with dopamine-blocking agents. Malnutrition and dehydration in the context of an organic brain syndrome and simultaneous treatment with lithium and antipsychotic agents can increase the risk. Mortality rates may be as high as 20-30% as a result of dehydration, aspiration, kidney failure, and respiratory collapse. Differential diagnosis of neuroleptic malignant syndrome includes infections, heat stroke, malignant hyperthermia, lethal catatonia, agitated delirium, thyrotoxicosis, serotonin syndrome, drug withdrawal, and anticholinergic or amphetamine, ecstasy, salicylate toxicity.

Serotonin Syndrome

Serotonin syndrome is characterized by a triad of mental status changes, autonomic hyperactivity, and neuromuscular abnormalities (see Chapter 63). It is the result of an excess agonism of the central and peripheral nervous system serotonergic receptors and can be caused by a range of drugs including SSRIs, valproate, and lithium. Drug-drug interactions that can cause serotonin syndrome include linezolid (an antibiotic that has monoamine oxidase inhibitor properties) and anti-migraine preparations used with an SSRI, as well as combinations of SSRI, trazodone, buspirone, and venlafaxine. It is generally self-limited and can resolve spontaneously after the serotonergic agents are discontinued. Severe cases require the control of agitation, autonomic instability, and hyperthermia as well as the administration of 5-HT_{2A} antagonists (e.g., cyproheptadine).

21.2 Psychotherapy

David R. DeMaso and Heather J. Walter

Psychotherapy in children may also be effective in reducing patient symptomatology. Effect sizes in research studies range from 0.71 to 0.84, which are as large as or larger than the effects of psychiatric medications or medicines for many physical illnesses. Despite benefit, only a minority of patients achieve the same level of functioning as average children, because in community settings the effect size of psychotherapy approaches zero. This poor response might reflect the fact that treatment in real-world community settings involves complex and co-occurring disorders, as opposed to the research or academic setting, where comorbid conditions are often excluded.

A variety of psychotherapeutic approaches exist with varying levels of evidence regarding their effectiveness. Differences between therapeutic approaches may be less pronounced in practice than in theory. The quality of the therapist–patient alliance consistently has been shown to be the strongest predictor of treatment outcome. A positive therapeutic relationship, expecting change to occur, facing problems assertively, increasing mastery, and attributing change to the participation in the therapy have all been connected to effective therapy.

The use of psychotherapy involves a series of interconnected steps including performing an assessment, deciding upon treatment and a monitoring plan, obtaining treatment assent or consent, and implementing treatment. Cognitive, emotional, and/or behavioral symptoms are identified that become the targets for evidence-based psychotherapeutic interventions. Psychotherapists ideally develop a treatment plan by combining known evidence-based practices about specific interventions with their clinical judgment to arrive at a specific intervention plan for the individual patient. It is not unusual for the psychotherapist to use elements from more than one treatment approach, including psychopharmacology.

BEHAVIOR THERAPY

Behavior therapy is based upon both classic (pavlovian) and operant (skinnerian) conditioning. Both of these approaches do not concern themselves with the inner motives of the individual, but instead address the antecedent stimuli and consequent responses. The treatment begins with a behavioral assessment with interview, observation, diary, and rating scale components, along with a functional analysis of the setting context, immediately preceding external events, and real-world consequences of the behavior. A treatment plan is then developed to modify the maladaptive functions of the behavior, using tools such as positive and negative reinforcement, social and tangible rewards, shaping, modeling, and prompting to increase positive behavior, and extinction, stimulus control, punishment, response cost, overcorrection, differential reinforcement of incompatible behavior, graded exposure/

systematic desensitization, flooding, modeling, and role playing to decrease negative behavior.

Behavior therapy has shown applicability to anxiety disorders, obsessive-compulsive and related disorders, posttraumatic stress disorder, behavior disorders, ADHD, nocturnal enuresis, autism spectrum disorder, and intellectual disability.

COGNITIVE-BEHAVIORAL THERAPY

Cognitive-behavioral therapy (CBT) is based on social and cognitive learning theories and extends behavior therapy to address the influence of cognitive processes on behavior. These cognitive processes include social information processing (automatic and controlled), fixed patterns of thinking or beliefs (cognitive schema), and emotional effects mediating cognitive attributions and behavior. CBT is problem-oriented treatment that seeks to identify and change cognitive distortions (e.g., learned helplessness or irrational fears), identify and avoid distressing situations, and identify and practice distress-reducing behavior. Self-monitoring (daily thought record), self-instruction (brief sentences asserting thoughts that are comforting and/or adaptive), and self-reinforcement (rewarding oneself) are key tools used to facilitate achievement of the CBT treatment goals.

CBT has shown applicability to the treatment of behavior, depressive, and anxiety disorders. Specially modified versions of CBT have shown applicability to the treatment of other disorders. ***Trauma-focused CBT*** involves a combination of psychoeducation, teaching effective relaxation, affective modulation, and cognitive coping and processing skills, engaging in a trauma narrative, mastering trauma reminders, and enhancing future safety and development, and is considered the first-line treatment for posttraumatic stress disorder. ***Dialectical behavioral therapy*** combines standard CBT with concepts of distress tolerance, emotional regulation, interpersonal effectiveness, and mindfulness drawn from Buddhist meditative practice. Dialectical behavioral therapy has shown promise for the treatment of borderline personality disorder, bipolar disorder, suicidal behavior, and other manifestations of emotional and behavioral dysregulation.

FAMILY THERAPY

Although family therapy covers a broad range of approaches, the core idea in family therapy is that the cause of problems in individuals is thought to lie in patterns of family interaction, with other family members helping to maintain the problem. Family dysfunction can take a variety of forms, including enmeshment, disengagement, role-reversal or confusion, and maladaptive communication patterns. Family therapy begins with an assessment of the family system, including observing patterns of interaction, assessing family beliefs and the meanings attached to behaviors, defining social and cultural contexts, exploring the presenting problem in the context of individual and family development, assessing the family's style of dealing with problems, and identifying family strengths and weaknesses. Family therapy techniques are drawn from 2 major theoretical models: structural and behavioral. Structural family therapy develops capacities believed to foster well-functioning families, including clear and flexible boundaries between individuals, well-defined roles, and an appropriate balance between closeness and independence. Behavioral family therapy focuses on behavioral sequences that occur in daily life, and attempts to interrupt unhelpful patterns and strengthen positive patterns through effective communication and problem solving.

Family therapy has shown applicability to anorexia and substance abuse, and for these disorders is the treatment of choice. For other disorders (e.g., depressive, anxiety, obsessive-compulsive, and behavior), the evidence is more limited.

PSYCHODYNAMIC PSYCHOTHERAPY

At the core of psychodynamic psychotherapy lies a *dynamic* interaction between different parts or aspects of the mind. This approach is based on the belief that much of one's mental activity occurs outside one's awareness. The patient is often unaware of internal conflicts because threatening or painful emotions, impulses, and memories are repressed. Behavior is then controlled by what the patient does not know about himself or herself. Therapy objectives are to increase self-understanding, increase acceptance of feelings, shift to mature defense mechanisms, and develop realistic relationships between self and others. This therapy is nondirective to allow the patient's characteristic patterns to emerge so that self-understanding and a corrective emotional experience can then be fostered by the therapist.

Psychodynamic psychotherapy has shown applicability for the treatment of emotional problems (e.g., anxiety, depression) as well as maladaptive aspects of personality. Limited applicability has been shown for behavior, eating, and trauma-related disorders. Brief, time-limited psychodynamic psychotherapy can be appropriate for youth who are in acute situational distress, while long-term therapy can be appropriate when the biological or social factors destabilizing the child's adaptation and development are chronic, or the psychological difficulties due to comorbidities are complex, or entrenched conflicts and developmental interferences are present.

SUPPORTIVE PSYCHOTHERAPY

Supportive psychotherapy aims to minimize levels of emotional distress through the provision of individual and contextual support. Treatment is focused on the here and now. The therapist is active and helpful in providing the patient with symptomatic relief by containing anxiety, sadness, and anger. The therapist provides education and encouragement to bolster a patient's existing coping mechanisms. The therapist also facilitates problem solving and social and instrumental support for contextual symptom-generating problems.

PARENTING INTERVENTIONS

Parenting interventions are based upon attachment and social learning theory. Attachment theory proposes that the quality of care provided to the child, particularly sensitivity and responsiveness, leads to a secure or insecure attachment, which in turn influences the development of internal working models of self and others. A history of consistent and sensitive care by a parent is expected to lead to the child developing a model of self as lovable and others as loving and helpful. Social learning theory hypothesizes that children's real-life experiences and exposures directly or indirectly shape behavior, and that new positive experiences and exposures can change behavior favorably.

Parenting interventions seek to address both attachment and social learning deficits by improving both the parent–child relationship and parenting skills. Core attachment skills include spending quality time with the child, increasing verbal interaction, showing physical affection, providing contingent praise, and engaging in child-directed play. Core parenting skills include increasing reinforcement of positive behaviors, decreasing reinforcement of negative behaviors, applying consequences for dangerous/destructive behavior, and making parental response predictable, contingent, and immediate.

Parenting interventions have shown applicability for the behavior disorders and ADHD.

21.3 Psychiatric Hospitalization

David R. DeMaso and Heather J. Walter

Psychiatric hospital programs are meant to address the serious risks and severe impairments caused by the most acute and complex forms of psychiatric disorder that cannot be managed effectively at any other level of care. Their goal is to produce rapid clinical stabilization that allows an expeditious, safe, and appropriate treatment transition to a less-intensive level of mental healthcare outside of the hospital.

High levels of illness severity combined with significant functional impairment signal a need for hospitalization. Admission criteria must include significant signs and symptoms of active psychiatric disorder(s). Functional admission indicators generally include a significant risk of self-harm and/or harm to others, although in some cases the patient is unable to meet basic self-care or healthcare needs, jeopardizing

well-being. Serious emotional disturbances that prevent participation in family, school, or community life can also rise to a level of global impairment that can only be addressed on an inpatient basis.

Discharge planning begins at the time of admission, when efforts are made to coordinate care with services and resources that are already in place for the child or adolescent in the community. Step-down care might be needed in partial hospital or residential settings if integrated services in a single location remain indicated after sufficient clinical stabilization has occurred in the hospital setting. Transition from the hospital entails active collaboration and communication with pediatric practitioners in the child's medical home.

Chapter 22

Somatic Symptom and Related Disorders

Patricia I. Ibeziako and David R. DeMaso

Pediatric psychosomatic medicine deals with the relation between physiologic and psychological factors in the causation or maintenance of disease states. The process whereby distress is experienced and/or expressed in physical symptoms is referred to as ***somatization*** or ***psychosomatic illness***. Even though somatic symptoms are present in virtually every psychiatric disorder, they are most prominent in the various somatic symptom disorders.

In the *Diagnostic Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5), illnesses previously referred to as somatoform disorders are defined as ***somatic symptom disorders***. Somatic symptom disorders are classified on the basis of distressing physical symptoms and excessive thoughts, feelings or behaviors in relation to these symptoms rather than the absence of a medical explanation for somatic symptoms. These disorders form a continuum that can range from pain to disabling neurological symptoms and they generally interfere with school, home life and peer relationships. The DSM-5 Somatic Symptom and Related Disorders category includes the following disorders related to children and adolescents: ***conversion disorder*** (or functional neurologic symptom disorder), ***somatic symptom disorder***, ***factitious disorder***, ***psychological factors affecting other medical conditions***, and ***other specified/unspecified somatic symptom disorders*** (Tables 22-1 through 22-5 identify the DSM-5 diagnostic criteria).

Multiple terms used to describe somatic symptom disorders include "functional," "psychosomatic," or "medically unexplained symptoms." Additionally, most patients are seen by general practitioners and specialists and may receive specialty-specific syndrome diagnoses such as visceral hyperalgesia, irritable bowel syndrome, chronic fatigue syndrome, or noncardiac chest pain. The diagnostic heterogeneity that exists across the different medical specialists contributes to the different diagnostic labels. Studies indicate a significant overlap in the symptoms and presentation of patients with somatic symptoms who have received different diagnoses from different specialties.

Moreover, functional syndromes share similarities in etiology, pathophysiology, neurobiology, psychological mechanisms, patient characteristics, and management and treatment response, which is indicative of a single spectrum of disorders. It is helpful for healthcare providers to avoid the dichotomy of approaching illness using a medical model in which diseases are considered as being either organic

Table 22-1 DSM-5 Diagnostic Criteria for Conversion Disorder or Functional Neurologic Symptom Disorder

A. One or more symptoms or deficits affecting voluntary motor or sensory function.
B. Clinical findings provide evidence of incompatibility between the symptom and recognized neurologic or medical conditions.
C. The symptom or deficit is not better explained by another medical or mental disorder.
D. The symptom or deficit causes clinically significant distress or impairment in social, occupational, or other important areas of functioning or warrants medical evaluation.

Specify symptom type: weakness or paralysis, abnormal movements, swallowing symptoms, speech symptom, attacks/seizures, or anesthesia/sensory loss, special sensory symptom (visual, olfactory, or hearing), or mixed symptoms.

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, p. 318.

Table 22-2 DSM-5 Diagnostic Criteria for Somatic Symptom Disorder

A. One or more somatic symptoms that are distressing or result in significant disruption of daily life.
B. Excessive thoughts, feelings or behaviors related to the somatic symptoms or associated health concerns as manifested by at least one of the following:
   1. Disproportionate and persistent thoughts about the seriousness of one's symptoms.
   2. Persistent high level of anxiety about health and symptoms.
   3. Excessive time and energy devoted to these symptoms or health concerns.
C. Although any 1 somatic symptom may not be continuously present, the state of being symptomatic is persistent.

Specify if:

With predominant pain (previously known as pain disorder in DSM IV-TR): for individuals whose somatic symptoms predominantly involve pain.

Persistent: A persistent course is characterized by severe symptoms, marked impairment, and long duration (more than 6 mo).

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, p. 311.

Table 22-3 DSM-5 Diagnostic Criterial for Psychological Factors Affecting Other Medical Conditions

A. A medical symptom or condition (other than a mental disorder) is present.
B. Psychological or behavioral factors adversely affect the medical condition in 1 of the following ways:
   1. The factors have influenced the course of the medical condition as shown by a close temporal association between the psychological factors and the development or exacerbation of, or delayed recovery from, the medical condition.
   2. The factors interfere with the treatment of the medical condition (e.g., poor adherence).
   3. The factors constitute additional well-established health risks for the individual.
   4. The factors influence the underlying pathophysiology, precipitating or exacerbating symptoms or necessitating medical attention.
C. The psychological and behavioral factors in Criterion B are not better explained by another mental disorder (e.g., panic disorder, major depressive disorder, posttraumatic stress disorder).

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, p. 322.

Table 22-4 DSM-5 Diagnostic Criteria for Factitious Disorders

Factitious Disorder Imposed on Self

A. Falsification of physical or psychological signs or symptoms, or induction of injury or disease, associated with identified deception.
B. The individual presents himself or herself to others as ill, impaired, or injured.
C. The deceptive behavior is evident even in the absence of obvious external rewards.
D. The behavior is not better explained by another mental disorder, such as delusional disorder or another psychotic disorder.

Factitious Disorder Imposed on Another (Previously Factitious Disorder by Proxy)

A. Falsification of physical or psychological signs or symptoms, or induction of injury or disease, in another, associated with identified deception.
B. The individual presents another individual (victim) to others as ill, impaired or injured.
C. The deceptive behavior is evident even in the absence of obvious external rewards.
D. The behavior is not better explained by another mental disorder, such as delusional disorder or another psychotic disorder.

Note: The perpetrator, not the victim, receives this diagnosis

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, p. 324.

Table 22-5 DSM-5 Diagnostic Criteria for Other Specified/Unspecified Somatic Symptom and Related Disorders

Other Specified

This category applies to presentations in which symptoms characteristic of a somatic symptom and related disorder that cause clinically significant distress or impairment in social, occupational, or other important areas of functioning predominate but do not meet full criteria for any of the disorders in the somatic symptom and related disorders diagnostic class.

Examples of presentations that can be specified using the "other specified" designation include the following:

1. Brief somatic symptom disorder: Duration of symptoms is <6 mo.
2. Brief illness anxiety disorder: Duration of symptoms is <6 mo.
3. Illness anxiety disorder without excessive health-related behaviors: Criterion D for illness anxiety disorder is not met.
4. Pseudocyesis: A false belief of being pregnant that is associated with objective signs and reported symptoms of pregnancy.

Unspecified

This category applies to presentations in which symptoms characteristic of a somatic symptom and related disorder that cause clinically significant distress or impairment in functioning predominate but do not meet criteria for any of the other disorders in the somatic symptom and related disorders diagnostic class.

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, p. 327.

or psychologically based. In contrast, a biobehavioral continuum of disease characterizes illness as occurring across a spectrum ranging from a biologic etiology on one end to predominantly a psychosocial etiology on the other.

EPIDEMIOLOGY

Between 10% and 30% of children worldwide experience physical symptoms that are described as "functional" or unexplained by a physical illness. Estimated prevalence varies greatly between studies based on the type of symptoms and the study methodology. The frequency and heterogeneity of complaints increase with age with symptoms occurring more frequently in females.

The majority of children with persistent complaints of abdominal pain meet criteria for functional abdominal pain or somatic symptom disorder with predominant pain in DSM-5. In a prospective study, patients with functional abdominal pain carry long-term vulnerability to anxiety that begins in childhood and persists into late adolescence and early adulthood, even if abdominal pain resolves.

Headaches, back pain, limb pain and chest pain, as well as other gastrointestinal symptoms, are also frequently occurring pain symptoms in adolescents. Prevalence rates of conversion disorder in adolescents are 0.3-10%. Nonepileptic seizures, loss of consciousness, and motor conversion symptoms are common somatic neurologic complaints across cultures.

RISK FACTORS

Family and Environmental

Genetic

A possible genetic etiology in somatization disorders is suggested by findings of a 29% concordance rate in monozygotic twin studies and 10-20% of 1st-degree relatives of patients meeting criteria for this disorder. Further evidence is seen in studies showing a familial link between somatic symptom disorders and other psychiatric disorders (e.g., higher rates of anxiety and depression in the family members).

Symptom Modeling

Multiple studies have found evidence that a significant proportion of patients with somatic symptom disorders had recently encountered similar symptoms in their local environment or live with family members who complain of similar physical symptoms (e.g., a child with nonepileptic seizures who has a parent or sibling with a seizure disorder).

Parental Responses

Parent beliefs about the significance of symptoms influence the amount of symptoms the child reports. Having a somatic complaint may be more acceptable or noticed in some households than the expression of strong emotions (e.g., anxiety, fear or anger). In such an environment, a child may garner minimal attention for emotional distress, but obtain more attention and sympathy for physical symptoms. Multiple studies have shown that parental protectiveness predicts child functional disability and parental responses (e.g., discouraging activity, expressing concern, and providing comfort) may serve to inadvertently reinforce and maintain illness behaviors.

School and Family Stressors

External environmental factors (e.g., school stress or change in family situation) are common in children presenting with somatic symptom disorders. Common school stressors include bullying, beginning the school year, fear of academic failure, or participation in extracurricular school activities. Dysfunction and less support within the family system are common in somatic symptom disorders. A transition within the family system including death of a family member, birth of a sibling, parental divorce, physical punishment by parents and an increase in the number of arguments between parents have all been linked to somatic symptoms. Nevertheless, there is a significant minority of patients with somatic symptom disorders who do not appear to have obvious psychosocial precipitants for their symptoms. It is unclear whether the absence of recorded stressful events in these patients is because they were unwilling or unable to report relevant stressors or if they were simply absent.

Trauma

Elevated rates of childhood trauma (e.g., childhood sexual, physical, or emotional abuse) have been found in patients with somatic symptom disorders although the trauma prevalence rates in studies vary widely.

Individual

Childhood Physical Illness

There does appear to be a connection between childhood physical illness and the later development of somatization. Many children with somatic symptom disorders have other medical conditions. An antecedent history (e.g., of an accident, viral illness) may trigger onset of symptoms and lead to prolonged recovery or recurrence of symptoms after illness should have subsided. Children who tend to somatize may have a tendency to experience normal somatic sensations as "intense, noxious and disturbing," referred to as *somatosensory amplification*. Children with somatic symptom disorders may also have histories of disabling and poorly explained physical symptoms.

Temperament/Coping Styles

Somatic symptoms have been found to be more common in children who are conscientious, sensitive, insecure, internalizers, anxious, and in those who strive for high academic achievement. Somatization may also occur in youngsters who are unable to verbalize emotional distress. Somatic symptoms are often seen as a form of psychological defense against intrapsychic distress that allows the child to avoid confronting anxieties or conflicts, a process referred to as *primary gain*. "Primary gain" is obtained by keeping the conflict from consciousness and minimizing anxiety. The symptoms may also lead to what is described as "secondary gain" if the symptom results in the child being allowed to avoid unwanted responsibilities or consequences.

Learned Behavior

Somatic complaints may be reinforced (e.g., through a decrease in responsibilities or expectations by others and/or through receiving attention and sympathy as a result of the physical symptoms). Many youngsters may have an antecedent underlying general medical condition that may then be reinforced by parental and/or peer attention as well as additional medical attention in the form of unnecessary tests and investigations.

Psychiatric Comorbidity

There is an association between somatization and other psychiatric illness, in particular depressive and anxiety disorders.

Other Biologic Factors

Research into the pathophysiology of somatic symptom disorders has suggested some unifying mechanisms, including aberrant functions of efferent neural pathways, such as the autonomic nervous system and the hypothalamic–pituitary axis, and alterations in central processing of sensory input. Hyperactivity of the anterior cingulate cortex has been found in patients with conversion disorder, along with impaired activity of the dorsolateral prefrontal cortex. In studies of chronic pain, including migraine and tension type headache, there appears to be progressive loss of gray matter density in brain structures involved in registering pain such as the somatosensory cortex, anterior cingulate cortex and insula. Additionally when there is a strong expectation of pain, the anterior insular cortex is activated in proportion to this expectation.

ASSESSMENT

The majority of patients with somatic symptom and related disorders present in the pediatric rather than mental health settings. It is important for pediatricians to make their diagnosis on the basis of positive symptoms and signs (distressing somatic symptoms plus abnormal thoughts, feelings, and behaviors in response to these symptoms) rather than the absence of a medical explanation. As such, the evaluation of suspected disorders should include an assessment of biologic, psychological, social, and developmental realms both separately and in relation to each other. An integrated approach where both pediatric and mental health clinician are involved in the assessment, management, and treatment is indicated.

Medical

The presence of a physical illness does not exclude the possibility of somatization playing an important role in the child's presentation. Somatic symptoms early in a disease course that can be directly attributed to a specific physical illness (e.g., acute respiratory illness) may evolve into psychologically based symptoms, particularly in situations in which the child may experience benefit from adopting the sick role. Somatic symptoms may also occur in excess of what would be expected of the symptoms experienced in an existing physical illness. Physical findings may occur secondary to the effects of the somatic symptom disorder, especially when chronic and/or severe (e.g., deconditioning, disuse atrophy and contractures from prolonged immobilization, nutritional deficiency, gastroparesis and constipation from chronic poor oral intake.)

A comprehensive medical work-up to rule out serious physical illness must be carefully balanced with efforts to avoid unnecessary and potentially harmful tests and procedures. The physical examination will find that the child's symptoms may fluctuate in different contexts, may be anatomically inconsistent or may be in excess of what would be expected from the physical findings.

Psychological

If somatization is suspected, psychiatric consultation should be included early in the diagnostic workup. The reason for consultation should be carefully explained to the family to help avoid the perception that their child's symptoms are not being taken seriously by the pediatric team (i.e., "it's in her head"). It should be explained that a complete work-up involves a thorough assessment of the physical and psychological domains of the child and the psychiatric consultation can provide further understanding of the origins of the child's distress, what perpetuates it and which treatments are likely to be most effective.

The mental health interview should include a careful assessment of the psychological and social stressors and risk factors including a thorough family psychiatric and medical history. The nature of current physical symptoms and any history of prior episodes of somatic symptoms should be included in the assessment, in addition to the child's emotional, social and academic functioning, coping strategies and family functioning. The evaluation should provide the clinical team with a biopsychosocial explanation of the child's symptoms, which will inform the treatment plan.

Differential Diagnoses

The primary differential diagnosis is between that of somatic symptom disorder and a physical illness. It is important, however, to be aware that these disorders are not mutually exclusive and often coexist. Mood and anxiety disorders frequently include the presence of physical symptoms which tend to remit with treatment of the primary mood or anxiety symptoms and which appear distinct from physical complaints seen in somatic symptom disorders. Chronic pain syndromes may be caused by fibromyalgia and small fiber autonomic neuropathy (see Chapter 168).

MANAGEMENT

With the completion of medical and psychological assessments, a multidisciplinary team meeting of medical and mental health clinicians should be arranged to review all the specialty evaluations and tests, discuss the formulation, diagnostic impressions and treatment recommendations. This should occur to ensure that a consensus has been reached regarding the diagnosis and treatment plan and to facilitate adequate and consistent communication among all providers.

An informing meeting or conference with the family should be facilitated after the above meeting to convey the multidisciplinary team's diagnostic impressions and treatment recommendations to the patient/family. Medical and mental health clinicians together should communicate the diagnosis (or diagnoses) in a way that families can understand using a comprehensive biopsychosocial formulation. Medical and psychiatric findings should be acknowledged and discussed. Patients and families with somatic symptom disorders often present with the belief that there is primarily a medical cause for their problem and psychosocial contributors are often resisted. Following exhaustive medical investigations which do not yield any unifying

results, labeling the symptoms as "psychiatric" can effectively shift the search for the cause onto family functioning, resulting in youngsters and parents feeling blamed for the symptoms. The team should help the family move towards an understanding of the mind–body connection and shift their approach from searching for the cause of the symptoms to increasing functioning. Providing education about the benefits of treatment and risks of nontreatment is helpful to move the family through the treatment steps.

Treatment

An integrated multidisciplinary rehabilitation model is the most suitable for patients with somatic symptom disorders. A rehabilitation model approach provides a useful framework for the treatment that shifts the focus away from finding a cure for symptoms, and instead emphasizes a return to normal adaptive functioning. This includes increased activities of daily living, improved nutrition, enhanced mobility, return to school and socialization with peers.

Cognitive behavioral interventions are evidence-based treatments of choice. Cognitive behavioral interventions modify symptom experience including pain perception and restore central nervous system abnormalities that are linked with functional impairment. Components of cognitive behavioral techniques (e.g., relaxation training, biofeedback, and hypnosis) can be used to teach patients the control they can have over certain physiological processes such as autonomic system activity. Cognitive restructuring is effective in addressing and altering dysfunctional thoughts regarding symptoms and their implications for functioning. Treatments that encourage active coping strategies, emotional expression and modulation and limit adolescent reliance on emotional support provided by parents are particularly helpful to more effectively reduce symptoms and improve functioning. Modifying parental response patterns that are overly protective and potentially reinforcing (e.g., allowing the child to sleep late or to stay home from school in response to symptoms) help to decrease disability.

Psychopharmacologic treatment may be considered when other psychiatric disorders are co-occurring, specifically depressive and anxiety disorders. A combination of pharmacotherapy, physical therapy, and psychological interventions in multicomponent management programs has been shown to be effective.

Treatment Setting

The majority of patients can be managed in the outpatient setting with appropriate mental health follow-up. Scheduled follow up visits with the primary care provider (PCP) and other specialists are important to maintain alliance and investment in treatment, prevent doctor shopping, and avoid unnecessary invasive tests and procedures.

Because of the nature of their symptoms, most patients with somatic symptom disorders do not present in mental health settings for their physical complaints and only patients displaying prominent emotional symptoms or who have a concurrent mental disorder are referred to psychiatric services. Medical specialists treat "their own" specialty functional somatic syndrome within their service as a natural consequence of the large number of patients with these disorders presenting at their clinics. The management in these clinics is often monodisciplinary and with primarily medically based treatments and interventions. The existence of various syndrome-specific clinics perpetuates the separate, specialty-dominated approach to somatic symptom disorders and can perpetuate fragmented care rather than moving toward a more integrated model. Although specialized clinics play an important role in the provision of the expertise needed in the evaluation of these patients, they are often not prepared to manage patients who have symptoms involving multiple organ systems. These patients may attend several clinics simultaneously and receive several, parallel, uncoordinated treatments.

A medical home model with mental health clinicians working in collaboration with PCPs and/or different medical specialists may prove to be the most suitable approach for patients with somatic symptom disorders. Collocated medical and mental health services improve communication, decrease fragmentation of services, and decrease the stigma and resistance some families may have with attending psychiatric clinics. The efficacy of a treatment program with comprehensive multidisciplinary services and cognitive behavioral treatment has been studied in a randomized, controlled trial, and the results showed immediate, clinically relevant benefits that were sustained at the 1-year follow-up.

Patients with profound and pervasive functional impairment likely will need more intensive psychiatric treatment (e.g., a medical-psychiatric partial hospital program or inpatient unit). Multidisciplinary inpatient rehabilitation programs have a great deal to offer these patients as they are designed to support both physical and psychological recovery. Families feel reassured that multidisciplinary staff can continue to monitor symptoms, thus ensuring that any missed diagnoses will be recognized quickly.

Children with a high level of impairment often miss a significant amount of school; communication with the school in such cases is often crucial in helping a successful transition back and improving overall functioning. In addition to discussions with the school guidance counselor and nurse, a letter for the school providing education and recommended approaches for patient's symptoms is often beneficial. Ongoing communication between the school and PCP for monitoring of further symptoms is recommended.

Chapter 23

Rumination and Pica

Emily R. Katz, Robert L. Kitts, and David R. DeMaso

23.1 Rumination Disorder

Emily R. Katz, Robert L. Kitts, and David R. DeMaso

Rumination disorder is the repeated regurgitation of food, where the regurgitated food may be rechewed, reswallowed, or spit out, for a period of at least 1 mo following a period of normal functioning. Regurgitation is typically frequent and daily; it does not occur during sleep. It is not caused by an associated gastrointestinal illness or other medical condition (e.g., gastroesophageal reflux or pyloric stenosis). It does not occur exclusively during the course of anorexia nervosa, bulimia nervosa, binge-eating disorder, or avoidant/restrictive food intake disorder. If the symptoms occur in the context of an intellectual developmental disorder or another neurodevelopmental disorder, they must be sufficiently severe to warrant additional clinical attention.

Weight loss and failure to make expected weight are common features in infants with rumination disorder. Infants may display a characteristic position of straining and arching the back with the head held back, making sucking movements with their tongue. In infants and older individuals with intellectual disability, the rumination behavior may appear to have a self-soothing or self-stimulating function. Malnutrition may occur in older children and adults, particularly when the regurgitation is associated with restricted food intake (which may be designed to avoid regurgitation in front of others). They may attempt to hide the regurgitation behavior or avoid eating among others.

EPIDEMIOLOGY

Originally thought of as a disorder predominantly seen in infants and those with intellectual disability, rumination disorder has also been recognized in healthy individuals across the life span. Prevalence data

for rumination disorder are inconclusive. In otherwise healthy children, this disorder typically appears in the first year of life, generally between the ages of 3 and 12 mo. The disorder can have an episodic course or occur continuously until treatment is initiated. In infants, the disorder frequently remits spontaneously, but can be protracted with problematic and even life-threatening malnutrition. Additional complications related to the secondary effects of malnutrition included growth delay and negative effect on development and learning potential.

ETIOLOGY AND DIFFERENTIAL DIAGNOSIS

Risk factors for rumination disorder in infants and young children include a disturbed relationship with primary caregivers, lack of an appropriately stimulating environment, neglect, stressful life situations, learned behavior reinforced by pleasurable sensations, distraction from negative emotions, and/or inadvertent reinforcement (attention) from primary caregivers. The differential diagnosis includes congenital gastrointestinal system anomalies, pyloric stenosis (see Chapter 329), Sandifer syndrome (see Chapter 323), gastroparesis, hiatal hernia (see Chapter 322), increased intracranial pressure, diencephalic tumors, adrenal insufficiency, and inborn errors of metabolism. Older children and adults with anorexia nervosa or bulimia nervosa may also engage in regurgitation because of concerns about weight gain. The diagnosis of rumination disorder is appropriate only when the severity of the disturbance exceeds that routinely associated with a concurrent physical illness or mental disorder.

TREATMENT

This first step in treatment begins with a behavioral analysis to determine if the disorder serves as a self-stimulation purpose and/or is socially motivated. The behavior may begin as self-stimulation, but it subsequently becomes reinforced and maintained by the social attention given to the behavior. The central focus of behavioral treatment is to reinforce correct eating behavior while minimizing attention to rumination. Diaphragmatic breathing and postprandial gum chewing when used as a competing response have been shown to be helpful. Aversive conditioning techniques (e.g., withdrawal of positive attention) are considered when a child's health is jeopardized.

Successful behavioral treatment requires the child's primary caregivers to be involved in the intervention. The caretakers need education and counseling around responding adaptively to the child's behavior as well as altering any maladaptive responses. There is no current evidence supporting a psychopharmacologic intervention for this disorder. In more severe or intractable cases (e.g., severe dehydration and malnutrition), an intensive integrated medical-behavioral treatment program afforded on a medical or medical-psychiatric unit may be necessary.

Bibliography is available at Expert Consult.

23.2 Pica

Emily R. Katz, Robert L. Kitts, and David R. DeMaso

Pica involves the persistent eating of nonnutritive, nonfood substances (e.g., paper, soap, plaster, charcoal, clay, wool, ashes, paint, earth) over a period of at least 1 mo. The eating behavior is inappropriate to the developmental level (e.g., the normal mouthing and tasting of objects in infants and toddlers) and, therefore, a minimum age of 2 yr is suggested. The eating behavior is not part of a culturally supported or socially normative practice. A diagnosis of pica may be assigned in the presence of any other feeding and eating disorder.

EPIDEMIOLOGY

Pica can occur throughout the lifetime, but occurs most commonly in childhood. It appears to be more common in those with intellectual disability and autism spectrum disorders, and to a lesser degree in obsessive-compulsive and schizophrenic disorders. The prevalence of pica is unclear, although it appears to increase with the severity of an intellectual disability. It usually remits in childhood but can continue into adolescence and adulthood. *Geophagia* (eating earth) is associated with pregnancy and is not seen as abnormal in some cultures (e.g., rural or preindustrial societies in parts of Africa and India). Children with pica are at increased risk for lead poisoning (see Chapter 721), iron-deficiency anemia (see Chapter 455), mechanical bowel problems, intestinal obstruction, intestinal perforations, dental injury, and parasitic infections. It can be fatal based on substances ingested.

ETIOLOGY AND DIFFERENTIAL DIAGNOSIS

Numerous etiologies have been proposed but not proved, ranging from psychosocial causes to physical ones. They include nutritional deficiencies (e.g., iron, zinc, and calcium), low socioeconomic factors (e.g., lead paint exposure), child abuse and neglect, family disorganization (e.g., poor supervision), mental disorder, learned behavior, underlying (but undetermined) biochemical disorder, and cultural and familial factors. The differential diagnosis includes anorexia nervosa (see Chapter 28), factitious disorder, and nonsuicidal self-injury in personality disorders. A separate diagnosis of pica should be made only if the eating behavior is sufficiently severe enough to warrant additional clinical attention.

TREATMENT

Combined behavioral, social, and medical approaches are generally indicated for pica. Assessment for neglect and family supervision combined with a psychiatric assessment for cooccurring mental disorders and developmental delay are important in developing an effective intervention strategy for pica. Behavioral treatment interventions, particularly applied behavioral analysis in patients with intellectual disability or autism spectrum disorders, have increasing evidence for being helpful. The sequelae related to an ingested item can require specific treatment (e.g., lead toxicity, iron-deficiency anemia, parasitic infestation). Ingestion of hair can require medical or surgical intervention for a gastric bezoar (see Chapter 334.2).

Chapter 24

Motor Disorders and Habits

*Colleen A. Ryan, Michael L. Trieu,
David R. DeMaso, and Heather J. Walter*

Motor disorders are interrelated sets of psychiatric symptoms characterized by abnormal motor movements and associated phenomena. In the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5), motors disorders include tic, stereotypic movement, and developmental coordination disorders. Tic disorders (Tourette, persistent motor or vocal tic, provisional tic) and stereotypic movement

disorder will be addressed in this chapter. Although not DSM-5 motor disorders, habits present as repetitive and often problematic motor behaviors (specifically thumb sucking and teeth grinding).

24.1 Tic Disorders

Colleen A. Ryan, Michael L. Trieu, David R. DeMaso, and Heather J. Walter

Tourette disorder **(TD),** ***persistent (chronic) motor or vocal tic*** **(PTD),** and provisional tic disorders (Table 24-1) are characterized by involuntary, rapid, repetitive, single or multiple motor and/or vocal/phonic tics that wax and wane in frequency but have persisted for more than 1 year since first tic onset (<1 year for provisional tic disorder). PTD is differentiated from TD in that PTD is limited to either motor or vocal tics (not both), whereas TD has both motor and vocal tics at some point in the illness (although not necessarily concurrently). The tic disorders are hierarchical in order (i.e., TD followed by PTD followed by provisional tic disorder), such that once a tic disorder at one level of the hierarchy is diagnosed, a lower hierarchy diagnosis cannot be made.

DESCRIPTION

Tics are sudden, rapid, recurrent, nonrhythmic motor movements or vocalizations. Simple motor tics (e.g., eye blinking, neck jerking, shoulder shrugging, extension of the extremities) are fast, brief movements involving one or a few muscle groups, while complex motor tics involve sequentially and/or simultaneously produced relatively coordinated movements that can seem purposeful (e.g., brushing back one's hair bangs, tapping the foot, imitating someone else's movement [echopraxia], or making a sexual or obscene gesture [copropraxia]). Simple vocal tics (e.g., throat clearing, sniffing, coughing) are solitary, meaningless sounds and noises, whereas complex vocal tics (e.g., partial words [syllables], words out of context, coprolalia [obscenities or slurs], palilalia [repeating one's own sounds or words], or echolalia [repeating the last heard word or phrase]) are meaningful utterances and verbalizations.

Sensory phenomena (premonitory urges) that precede and trigger the urge to tic have been described. Individuals with tics can suppress them for varying periods of time, particularly when external demands exert their influence, when deeply engaged in a focused task or activity, or during sleep. Tics are often suggestible and are worsened by anxiety, excitement, or exhaustion. Although parents have described increasing frequency of tics at the end of the day, research has not supported volitional suppressing of tics leading to tic rebound.

Table 24-1 DSM-5 Diagnostic Criteria for Tic Disorders

Note: A tic is a sudden, rapid, recurrent, nonrhythmic motor movement or vocalization.

TOURETTE'S DISORDER

A. Both multiple motor and one or more vocal tics have been present at some time during the illness, although not necessarily concurrently.
B. The tics may wax and wane in frequency but have persisted for more than 1 year since first tic onset.
C. Onset is before age 18 years.
D. The disturbance is not attributable to the physiological effects of a substance (e.g., cocaine) or another medical condition (e.g., Huntington's disease, postviral encephalitis).

PERSISTENT (CHRONIC) MOTOR OR VOCAL TIC DISORDER

A. Single or multiple motor or vocal tics have been present during the illness, but not both motor and vocal.
B. The tics may wax and wane in frequency but have persisted for more than 1 year since first tic onset.
C. Onset is before age 18 years.
D. The disturbance is not attributable to the physiological effects of a substance (e.g., cocaine) or another medical condition (e.g., Huntington's disease, postviral encephalitis).
E. Criteria have never been met for Tourette's disorder.

Specify if:
With motor tics only
With vocal tics only

PROVISIONAL TIC DISORDER

A. Single or multiple motor and/or vocal tics.
B. The tics have been present for less than 1 year since first tic onset.
C. Onset is before age 18 years.
D. The disturbance is not attributable to the physiological effects of a substance (e.g., cocaine) or another medical condition (e.g., Huntington's disease, postviral encephalitis).
E. Criteria have never been met for Tourette's disorder or persistent (chronic) motor or vocal tic disorder.

From the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, p. 81.

CLINICAL COURSE

Onset of tics is typically between ages 4 and 6 yr. Peak severity occurs between ages 10 and 12 yr, with marked attenuation of tic severity in most individuals (65%) by age 18-20 yr. A small percentage will have worsening tics into adulthood. New onset of tics in adulthood is very rare and most often is associated with exposure to drugs or insults to the central nervous system. Tics manifest similarly in all age groups and change in affected muscle groups and vocalizations over time. Some individuals may have tic-free periods of weeks to months.

EPIDEMIOLOGY

Prevalence rates for all tics range from 6-18% for boys and 3-11% for girls, with the rate of TD alone estimated as 0.3-0.8%. In general, PTD/TD has a male preponderance with a gender ratio varying from 2 : 1 to 4 : 1. Evidence supports higher rates in white compared to African-American or Hispanic youth.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis includes the repetitive movements of childhood (Table 24-2). Tics may be difficult to differentiate from stereotypies. Although stereotypies may resemble tics, stereotypies are typically rhythmic movements and do not demonstrate the change in body location or movement type over time that is typical of tics. Compulsions may be difficult to differentiate from tics when tics have premonitory urges. Tics should be differentiated from a variety of developmental and benign movement disorders (e.g., benign paroxysmal torticollis, Sandifer syndrome, benign jitteriness of newborns, and shuddering attacks). Tics may present in various neurologic illnesses (e.g., Wilson disease, neuroacanthocytosis, Huntington syndrome, and a variety of frontal-subcortical brain lesions); it is rare for tics to be the only manifestation of these disorders. Individuals presenting with tics in the context of declining motor or cognitive function should be referred for neurologic assessment. Some substances/medications that are reported to worsen tics include stimulants, selective serotonin reuptake inhibitors, lamotrigine, and cocaine. If tics develop in close temporal relationship to the use of a substance/medication and then remit when use of the substance is discontinued, a causal relationship is possible. Although a long-time clinical concern, there is no scientific evidence in controlled studies that stimulants increase tics.

COMORBIDITIES

Co-occurring psychiatric disorders are common, often with both the patient and family viewing the accompanying condition as more problematic than the tics per se. There is a bidirectional association between PTD/TD (especially TD) and obsessive-compulsive disorder (OCD; see Chapter 25), with 20-60% of TD patients meeting OCD criteria and 20-40% of OCD patients reporting tics (Fig. 24-1). Attention-deficit/hyperactivity disorder (ADHD; see Chapter 33) co-occurs in approximately 50% of all childhood PTD/TD, but estimates

Table 24-2 Repetitive Movements of Childhood

	DESCRIPTION	TYPICAL DISORDERS WHERE PRESENT
Tics	Sudden rapid, recurrent, nonrhythmic, stereotyped, vocalization or motor movement	Transient tics, Tourette disorder, persistent tic disorder
Dystonia	Involuntary, sustained, or intermittent muscle contractions that cause twisting and repetitive movements, abnormal postures, or both	DYT1 Gene, Wilson, myoclonic dystonia, extrapyramidal symptoms caused by dopamine blocking agents
Chorea	Involuntary, random, quick, jerking movements, most often of the proximal extremities, that flow from joint to joint. Movements are abrupt, nonrepetitive, and arrhythmic and have variable frequency and intensity	Sydenham chorea, Huntington chorea
Stereotypies	Stereotyped, rhythmic, repetitive movements or patterns of speech, with lack of variation over time	Autism, stereotypic movement disorder, intellectual disability
Compulsions	A repetitive, excessive, meaningless activity or mental exercise that a person performs in an attempt to avoid distress or worry	Obsessive-compulsive disorder, anorexia, body dysmorphic disorder, trichotillomania, excoriation disorder
Myoclonus	Shock-like involuntary muscle jerk that may affect a single body region, one side of the body, or the entire body; may occur as a single jerk or repetitive jerks	Hiccups, hypnic jerks, Lennox-Gastaut syndrome, juvenile myoclonic epilepsy, mitochondrial encephalopathies, metabolic disorders
Akathisia	Unpleasant sensations of "inner" restlessness, often prompting movements in an effort to reduce the sensations	Extrapyramidal adverse effects from dopamine blocking agents; anxiety
Volitional behaviors	Behavior that may be impulsive or due to boredom like tapping peers, making sounds (animal noises)	Attention-deficit/hyperactivity disorder, oppositional defiant disorder, sensory integration disorders

Adapted from Murphy TK, Lewin AB, Storch EA, et al: Practice parameter for the assessment and treatment of children and adolescents with chronic tic disorders, J Am Acad Child Adolesc Psychiatry *52(12):1341–1359, 2013.*

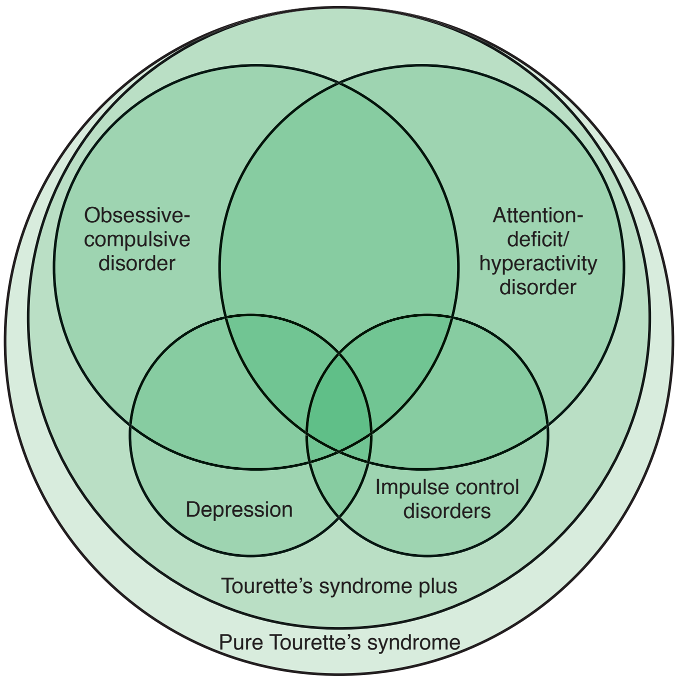

Figure 24-1 **Schematic representation of the behavioral spectrum in Tourette syndrome.** The size of each area is proportional to the estimated prevalence of the symptoms; the background color intensity is proportional to the complexity of the clinical presentation. *From Cavanna AE, Seri S: Tourette's syndrome. BMJ 347:f4964, 2013.*

in clinically referred patients suggest much higher rates (60-80%). PTD/TD is often accompanied by behavior problems including poor frustration tolerance, temper outbursts, and oppositionality. Learning disabilities have been found in more than 20% of these patients. The co-occurrence of anxiety and depression also has been observed. Some patients with PTD/TD will display symptoms of ***autism spectrum disorders*** (**ASDs**; see Chapter 30); careful assessment is required to determine which disorder is primary.

ETIOLOGY

Tics are proposed to be the result of dysfunctional corticostriatal–thalamocortical motor pathways in the basal ganglia, striatum, and frontal lobes associated with abnormalities in the dopamine, serotonin and norepinephrine neurotransmitter systems. Male predominance in PTD/TD may be attributable to influences of sex hormones on the neurodevelopment of these motor pathways, as reflected by the effects of antiandrogens in the treatment of TD.

Family studies suggest a 10-100–fold increase in the risk of PTD/TD among 1st-degree relatives compared to rates in the general population. Twin studies also support a genetic link, with approximately 80% of monozygotic twins and 30% of dizygotic twins showing concordance for PTD/TD. To date, candidate-gene association and nonparametric linkage studies have not shown specific susceptibility genes for PTD/TD.

Autoimmune mediated mechanisms have been hypothesized as having a potential etiologic role in some tic disorders. The ***pediatric autoimmune neuropsychiatric disorder associated with streptococcal infection*** (**PANDAS**; see Chapter 183) designation has been used to describe cases of acute childhood onset of OCD and/or tics following a streptococcal infection. More recently, **PANS *(pediatric acute-onset neuropsychiatric syndrome)*** has been used to describe a subtype of acute childhood onset OCD (tics are not a required feature) in which a link to a prior streptococcal infection is not evident suggesting that other infectious agents may also be responsible (Table 24-3). In addition to a diagnosis of OCD and/or tics, children with PANS/PANDAS have been reported to have symptoms of separation anxiety, nightmares, personality change, oppositional behaviors, and deterioration in math skills and handwriting. Although some studies suggest a prior history of infections may increase the risk for developing tic disorder, this remains controversial.

Premorbid stress has been hypothesized to act as a sensitizing agent in the pathogenesis of TD among susceptible individuals by affecting

Table 24-3 Diagnostic Criteria Proposed for Pediatric Acute-Onset Neuropsychiatric Syndrome (PANS)

CRITERION	DESCRIPTION
I.	Abrupt, dramatic onset of obsessive-compulsive disorder or severely restricted food intake
II.	Concurrent presence of additional neuropsychiatric symptoms, with similarly severe and acute onset, from at least 2 of the following 7 categories (see text for full description): 1. Anxiety 2. Emotional lability and/or depression 3. Irritability, aggression and/or severely oppositional behaviors 4. Behavioral (developmental) regression 5. Deterioration in school performance 6. Sensory or motor abnormalities 7. Somatic signs and symptoms, including sleep disturbances, enuresis or urinary frequency
III.	Symptoms are not better explained by a known neurologic or medical disorder, such as Sydenham chorea, systemic lupus erythematosus, Tourette disorder or others. *Note:* The diagnostic work-up of patients suspected of PANS must be comprehensive enough to rule out these and other relevant disorders. The nature of the co-occurring symptoms will dictate the necessary assessments, which may include MRI scan, lumbar puncture, electroencephalogram or other diagnostic tests.

From Swedo SE, Leckman JF, Rose NR: From research subgroup to clinical syndrome: modifying the PANDAS criteria to describe PANS (Pediatric Acute-onset Neuropsychiatric Syndrome). Pediatr Therapeut *2:113, 2012, Table 2.*

stress responsive biologic systems such as the hypothalamic–pituitary–adrenal axis.

SEQUELAE

Many individuals with mild to moderate tics express little to no distress or functional impairment and may even be unaware of their tics. Even individuals with moderate to severe tics can experience little functional impairment, but psychological distress may occur. Uncommonly, the presence of tics can lead to social isolation, social victimization, inability to work or attend school, or impaired quality of life.

SCREENING

Pediatricians should routinely screen for unusual movements and vocalizations. As an adjunct to a verbal screen, commonly used broadband symptom rating scales such as the *Child Behavior Checklist* (CBCL) and the *Swanson, Nolan, and Pelham* (SNAP) include specific tic questions. Often families are unaware that frequent sniffing, coughing, or blinking may be indicative of tics, attributing these behaviors to medical problems (e.g., allergies, visual problems). A careful assessment of the timing, triggers, and specific characteristics may differentiate tics from other medical problems. If differentiation is difficult, a referral to a pediatric specialist in the affected system is warranted.

ASSESSMENT

If the screening suggests the presence of a tic disorder, a more comprehensive evaluation should ensue, including the age of onset, types of tics, tic frequency, alleviating and aggravating factors, and a family history of tics. Symptom rating scales specific for tics (e.g., the *Motor tic, Obsessions and compulsions, Vocal tic Evaluation Survey* [MOVES], *Tic Self Report Scale*, *Tourette's Disorder Scale*, *Parent Tic Questionnaire* (PTQ; hppt://www.uab.edu/ot/practice/tourette-syndrome-clinic/parent-tic-questionnaire), and the *Child Tourette's Disorder Impairment Scale–Parent Version* can supplement the assessment. For clinician-rated tic severity, the most commonly used instrument is the *Yale Global Tic Severity Scale* (YGTSS); the *Tourette Syndrome Severity Scale* (TSSS), and the *Tourette Syndrome Global Scale* (TSGS) also can be useful.

A medical workup should be considered for new-onset tics, particularly for presentations characterized by sudden onset, atypicality, or mental status abnormalities. Basic laboratory measures (hemogram, renal/hepatic function panel, thyroid panel and ferritin along with urine drug screen for adolescents) should be considered. For new sudden (overnight) onset or severe symptom exacerbation, pediatricians may assess for co-occurring acute infection (e.g., culture, rapid viral tests, etc.). Electroencephalogram and brain imaging are not routinely recommended and should be reserved for cases with other neurologic findings that might suggest an autoimmune encephalitis syndrome (limbic encephalitis) (see Chapter 598.4). Cooccurring psychiatric disorders (e.g., OCD, ADHD, ASD) should be investigated.

TREATMENT

The decision to treat tics is made with the child and family based upon the level of impairment and distress caused by the tics. If tics are mild in severity, there may be no need for intervention after psychoeducation is provided.

Psychoeducation should include common symptom presentations, implications of co-occurring conditions, course and prognosis, and treatment options (including no treatment). The youth's typical exacerbating and alleviating factors should be reviewed. The clinician can direct the family and youth to informational websites, including the Tourette Syndrome Association (www.tsa-usa.org) or the Tourette Syndrome "Plus" website (www.tourettesyndrome.net).

Nearly 75% of children with TD/PTD receive some form of classroom accommodation (most often ignoring the tics and permission to leave the room as needed). The accommodations may need to be formalized in an ***Individualized Education Plan*** **(IEP)** or 504 Plan.

Referral to a behavioral treatment specialist should be considered when tics are distressing or functionally impairing. The behavioral intervention with the strongest empirical support is ***habit reversal therapy*** **(HRT)**. The typical components of HRT include premonitory urge awareness training, building a competing response to the urge to tic, and social support. In a large randomized trial comparing an HRT protocol to a psychosocial control, the effect size favoring the intervention was 0.64; nearly all intervention subjects were also prescribed medication. To date, there are no studies comparing HRT to medication or combined (medication plus HRT) therapy.

Behavioral treatment may also address less-adaptive coping strategies (e.g., avoidance, social withdrawal) that develop secondary to tics and contribute to impairment. Skill-based therapies such as cognitive-behavioral therapy can be beneficial in reducing maladaptive coping strategies, anxiety, and compulsive behavior.

Medications should be considered when the tics are causing severe impairment in the quality of life, or when medication-responsive psychiatric comorbidities are present that target both tic symptoms and comorbid conditions. The only 2 FDA-approved medications to treat TD are haloperidol and pimozide, although most clinicians use atypical antipsychotics (risperidone) before the FDA-approved agents because of the more favorable side-effect profile of the atypicals. Others use α_2-agonists as 1st-line agents because of their less-adverse side-effect profile compared to the antipsychotics.

The α_2-adrenergic agonists (clonidine and guanfacine) have demonstrated an effect size of 0.5 for amelioration of tics. A meta-analysis found that agonist trials enrolling subjects with comorbid ADHD demonstrated a much higher effect size (0.68) than trials enrolling subjects without comorbid ADHD (0.15). The starting dose for clonidine is 0.025-0.05 mg/day with gradual increases up to 0.1-0.4 mg/day, administered in divided doses (3-4 times a day). A transdermal patch of clonidine is available, as is a sustained-release formulation that has been FDA-approved for the treatment of ADHD, but has not been studied for the treatment of tics. Sedation and low blood pressure are

common side effects that require careful monitoring, particularly when initiating treatment. The role of guanfacine, which is a less-sedating α_2-agonist, has not been firmly established but trials are underway.

The D_2 dopamine receptor-blocking medications (haloperidol and pimozide) are effective in reducing tics, but the side-effect burden (e.g., extrapyramidal symptoms) have limited their use as 1st-line treatment. Risperidone, an atypical antipsychotic medication, has appeared in 4 randomized control trials to be an effective treatment, although concerns for neuromotor and metabolic side effects exist. The starting dose for risperidone is 0.125-0.5 mg/day with a usual dose range of 0.75-3.0 mg/day.

The side effects of all antipsychotic medications warrant close monitoring: abnormal movements should be monitored periodically using a standardized methodology (such as the *Abnormal Involuntary Movement Scale [AIMS] checklist*); blood pressure, body mass index and fasting glucose and lipids should be checked at baseline and at regular intervals thereafter, according to standard guidelines. Consideration of weight management interventions and increased monitoring of blood glucose and lipid levels should be implemented if weight gain exceeds 90th percentile body mass index for age, or a change of 5 body mass index units occurs in youths who were obese at the beginning of treatment. In patients with a personal or family history of cardiac abnormalities, including syncope, palpitations, arrhythmias, or sudden unexplained death, a baseline electrocardiogram with subsequent monitoring should be considered, along with cardiology consultation. Alternative pharmacology should be considered if the resting heart rate exceeds 130 beats/min, or the PR, QRS, and QTc exceed 200, 120, and 460 msec, respectively.

Children with tic disorders may benefit from selective serotonin reuptake inhibitors (SSRIs) for the treatment of comorbid OCD, anxiety, or depressive disorders. Augmentation of SSRIs with an atypical antipsychotic medication has been a consideration in patients with co-occurring tic disorders and OCD responding poorly to an SSRI alone. The presence of tics does not preclude the use of stimulants to address comorbid ADHD. However, close clinical monitoring is required for possible exacerbation of tics during stimulant treatment. Anger and rage outbursts are not uncommon among youth with tics (up to 80% in clinically referred samples). Behavioral therapies that address anger management may be useful. There are no controlled pharmacologic studies in youth with tics disorders with anger outbursts. There also is no scientific evidence to support the use of deep brain stimulation, repetitive magnetic stimulation, and dietary supplements in the treatment of TD/PTD.

24.2 Stereotypic Movement Disorder

Colleen A. Ryan, Michael L. Trieu, David R. DeMaso, and Heather J. Walter

In DSM-5, ***stereotypic movement disorder*** **(SMD)** is defined as a neurodevelopmental disorder characterized by repetitive, seemingly driven, and apparently purposeless motor behavior (stereotypy) that interferes with social, academic, or other activities that may result in self-injury. The onset of SMD is the early developmental period (often before age 3 yr), and the symptoms are not attributable to the physiologic effects of a substance or neurologic condition and are not better explained by another neurodevelopmental or mental disorder. The disorder is considered mild if symptoms are easily suppressed by sensory stimulus or distraction, and severe if continuous monitoring and protective measures are required to prevent serious injury, with moderate falling between mild and severe.

DESCRIPTION

Examples of stereotypic movements include hand shaking or waving, body rocking, head banging, self-biting, and hitting one's own body. The presentation depends on the nature of the stereotypic movement and level of the child's awareness of the behavior. Among typically developing children, the repetitive movements may be stopped when attention is directed to them or when the child is distracted from performing them. Among children with neurodevelopmental disorders, the behaviors are typically less responsive to such efforts. Each individual presents with his or her own uniquely patterned behavior. Stereotypic movements may occur many times during a day, lasting a few seconds to several minutes or longer. The behaviors may occur in multiple contexts, including when the individual is excited, stressed, fatigued, or bored.

CLINICAL COURSE

Stereotypic movements typically begin within the first 3 yr of life. In children who develop complex motor stereotypies, the great majority exhibit symptoms before 24 mo of age. In most typically developing children, these movements resolve over time. Among individuals with intellectual disability, the stereotyped behaviors may persist for years, although the pattern may change over time.

EPIDEMIOLOGY

Simple stereotypic movements (e.g., rocking) are common in typically developing young children. Self-injurious habits, such as self-biting or head banging, can occur in up to 25% of typically developing toddlers, but they are almost invariably associated with developmental delay in children older than age 5 yr. Complex stereotypic movements are much less common (occurring in approximately 3-4% of children). Between 4% and 16% of individuals with intellectual disability engage in stereotypic movements.

COMORBIDITY

Stereotypic movements are a common manifestation of a variety of neurogenetic disorders, such as Lesch-Nyhan syndrome, Rett syndrome (see Chapter 599), fragile X syndrome (see Chapter 81), Cornelia de Lange syndrome, and Smith-Magenis syndrome.

DIFFERENTIAL DIAGNOSIS

According to DSM-5, stereotypic movements must be differentiated from normal development, **ASDs**, tic disorders, **OCDs**, and other neurologic and medical conditions. Simple stereotypic movements occurring in the context of normal development usually resolve with age. Stereotypic movements may be a presenting symptom of ASD, but SMD does not include the deficits in social communication characteristic of ASD. When ASD is present, SMD is diagnosed only when there is self-injury or when the stereotypic behaviors are sufficiently severe to become a focus of treatment. Typically, SMD has an earlier age of onset than the tic disorders, and the movements are fixed in their pattern. SMD is distinguished from OCD by the absence of obsessions as well as the nature of the repetitive behaviors, which in OCD are purposeful (e.g., in response to obsessions). The diagnosis of stereotypic movements requires the exclusion of habits, mannerisms, paroxysmal dyskinesias, and benign hereditary chorea. A neurologic history and examination are required to assess features suggestive of other disorders, such as myoclonus, dystonia, and chorea.

ETIOLOGY

There is a possible evolutionary link between repetitive abnormal grooming-like behaviors and early human experience with adversity. Brain regions implicated in this model (e.g., amygdala and hippocampus) are those involved in navigating human experience through unpredictable, anxiety-provoked emotional states as well as regions (e.g., nucleus accumbens) related to pleasure and reward seeking. The latter involves the hypothesis that individuals experience some level of gratification from performing the habit behavior.

Social isolation with insufficient stimulation (e.g., severe neglect; see Chapter 40) is a risk factor for self-stimulation that may progress into stereotypies (particularly repetitive rocking or spinning). Environmental stress may trigger stereotypic behaviors. Repetitive self-injurious behavior may be a behavioral phenotype in neurogenetic syndromes (e.g., Lesch-Nyhan, Rett, and Cornelia de Lange syndromes). Lower cognitive functioning is also linked to greater risk of stereotypic behaviors.

TREATMENT

The initial approach to helping children with mild stereotypy is for parents to ignore the undesired behavior, encourage substitute behavior, and not convey worry to their child. These behaviors may disappear with time and elimination of attention in young children. However, in children with neurodevelopmental disorders, stereotypies are more refractory to treatment than in normally developing children, and may necessitate referral to a behavioral psychologist and/or child and adolescent psychiatrist for behavioral and/or psychopharmacologic management. The pediatrician should consider and rule out neglect of the child, which can be associated with repetitive rocking, spinning, or other stereotypic movements.

Behavior therapy is the mainstay of treatment, using a variety of strategies including habit reversal, relaxation training, self-monitoring, contingency management, competing responses, and negative practice. The environment should also be modified to reduce risk of injury to those engaging in self-injurious behavior.

Atypical antipsychotic medications appear to be helpful in reducing stereotypic movements in youth with ASD. Patients with co-occurring with anxiety and obsessive-compulsive behaviors treated with SSRIs for these disorders may show improvement in their stereotypic movements.

HABITS

Habits involve an action or pattern of behavior that is repeated often. Habits are common in childhood and range from benign and transient (thumb sucking, nail biting) to more problematic (trichotillomania, bruxism). In DSM-5, habits are not included as a diagnostic category as they are not viewed as disorders causing clinically significant distress or impairment in functioning. Treatment with HRT has been effective as a 1st-line approach (Table 24-4).

Table 24-4 Components of Habit Reversal Procedure

Increase Individual's Awareness of Habit
Response description—have individual describe behavior to therapist in detail while reenacting the behavior and looking in a mirror.
Response detection—inform individual of each occurrence of the behavior until each occurrence is detected without assistance.
Early warning—have individual practice identifying earliest signs of the target behavior.
Situation awareness—have individual describe all situations in which the target behavior is likely to occur.
Teach Competing Response to Habit
The competing response must result in isometric contraction of muscles involved in the habit, be capable of being maintained for 3 min, and be socially inconspicuous and compatible with normal ongoing activities but incompatible with the habit (e.g., clenching one's fist, grasping and clenching an object). For vocal tics and stuttering, deep relaxed breathing with a slight exhale before speech has been used as the competing response.
Sustain Compliance
Habit inconvenience review—have individual review in detail all problems associated with target behavior.
Social support procedure—family members and friends provide high levels of praise when a habit-free period is noted.
Public display—individual demonstrates to others that he or she can control the target behavior in situations in which the behavior occurred in the past.
Facilitate Generalization—Symbolic Rehearsal Procedure
For each situation identified in situation awareness procedure, individual imagines himself or herself beginning the target behavior but stopping and engaging in the competing response.

From Carey WB, Crocker AC, Coleman WL, Elias ER, Feldman HM, editors: Developmental-behavioral pediatrics, *ed 4, Philadelphia, 2009, Elsevier/Saunders, Table 65-4, p. 639.*

Thumb Sucking

Thumb sucking is common in infancy and in as many as 25% of children age 2 yr and 15% of children age 5 yr. Thumb sucking beyond 5 yr may be associated with sequelae (paronychia, anterior open bite). Like other rhythmic patterns of behavior, thumb sucking is self-soothing. Basic behavioral management, including encouraging parents to ignore thumb sucking and instead focus on praising the child for substitute behaviors, is often effective treatment. Simple reminders and reinforcers, such as giving the child a sticker (or other rewards) for each block of time that he or she does not suck the thumb can also be considered. Although some suggest the use of noxious agents (bitter salves) this approach should rarely be necessary.

Bruxism

Bruxism or teeth grinding is common (5-30% of children), can begin in the first 5 yr of life, and may be associated with daytime anxiety. Persistent bruxism can manifest as muscular or temporomandibular joint pain. Untreated bruxism can cause problems with dental occlusion. Helping the child find ways to reduce anxiety might relieve the problem; bedtime can be made more relaxing by reading or talking with the child and allowing the child to discuss fears. Praise and other emotional support are useful. Persistent bruxism requires referral to a dentist given the risk for dental occlusion.

Chapter 25

Anxiety Disorders

David R. Rosenberg and Jennifer A. Chiriboga

Anxiety, defined as dread or apprehension is not considered pathologic, is seen across the life span, and can be adaptive (e.g., the anxiety one might feel during an automobile crash). Anxiety has both a cognitive and behavioral component, expressed in worrying and wariness, and a physiologic component, mediated by the autonomic nervous system. Anxiety disorders are characterized by pathologic anxiety in which anxiety becomes disabling, interfering with social interactions, development, and achievement of goals or quality of life, and can lead to low self-esteem, social withdrawal, and academic underachievement. The average age of onset of anxiety disorder is 11 yr. Diagnosis of a particular anxiety disorder in a child requires significant interference in the child's psychosocial and/or academic or occupational functioning, which can occur even with subthreshold symptoms that do not meet criteria in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5). Anxiety may have physical manifestations such as weight loss, pallor, tachycardia, tremors, muscle cramps, paresthesias, hyperhidrosis, flushing, hyperreflexia, and abdominal tenderness.

Separation anxiety disorder (**SAD**), childhood-onset social phobia or social anxiety disorder, generalized anxiety disorder (**GAD**), obsessive-compulsive disorder (**OCD**), phobias, posttraumatic stress disorder (**PTSD**), and panic disorder (**PD**) are all defined by the occurrence of either diffuse or specific anxiety, often related to predictable situations or cues. Anxiety disorders are the most common psychiatric disorders of childhood; they occur in 5-18% of all children and adolescents, prevalence rates comparable to physical disorders such as asthma and diabetes. Anxiety disorders are often comorbid with other psychiatric and medical disorders (including a second anxiety disorder); significant impairment in day-to-day functioning is common. High levels of fear in adolescence are also a significant risk factor for experiencing later episodes of major depression in adulthood. Anxiety

and depressive disorder in adolescence predict increased risk of anxiety and depressive symptoms (including suicide attempts) in adulthood, underscoring the need to diagnose and treat these underreported, yet prevalent, conditions early.

Because anxiety is both a normal phenomenon and, when highly activated, strongly associated with impairment, the pediatrician must be able to differentiate normal anxiety from abnormal anxiety across development. Anxiety has an identifiable developmental progression for most children; most infants exhibit stranger wariness or anxiety beginning at 7-9 mo of age. Behavioral inhibition to the unfamiliar (withdrawal or fearfulness to novel stimuli associated with physiologic arousal) is evident in approximately 10-15% of the population at 12 mo of age and is moderately stable. Most children who show behavioral inhibition do not develop impairing levels of anxiety. A family history of anxiety disorders and maternal over involvement or enmeshment predicts later clinically significant anxiety in behaviorally inhibited infants. The infant who is excessively clingy and difficult to calm during pediatric visits should be followed for signs of increasing levels of anxiety.

Preschoolers typically have specific fears related to the dark, animals, and imaginary situations, in addition to normative separation anxiety. Preoccupation with orderliness and routines (*just right* phenomena) often takes on a quality of anxiety for preschool children. Parents' reassurance is usually sufficient to help the child through this period. Although most school-age children abandon the imaginary fears of early childhood, some replace them with fears of bodily harm or other worries (Table 25-1). In adolescence, general worrying about school performance and worrying about social competence are common and remit as the teen matures.

Table 25-1	DSM-5 Diagnostic Criteria for Specific Phobia

Diagnostic Criteria

A. Marked fear or anxiety about a specific object or situation (e.g., flying, heights, animals, receiving an injection, seeing blood).

Note: In children, the fear or anxiety may be expressed by crying, tantrums, freezing, or clinging.

B. The phobic object or situation almost always provokes immediate fear or anxiety.

C. The phobic object or situation is actively avoided or endured with intense fear or anxiety.

D. The fear or anxiety is out of proportion to the actual danger posed by the specific object or situation and to the sociocultural context.

E. The fear, anxiety, or avoidance is persistent, typically lasting for 6 mo or more.

F. The fear, anxiety, or avoidance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning.

G. The disturbance is not better explained by the symptoms of another mental disorder, including fear, anxiety and avoidance or situations associated with panic-like symptoms or other incapacitating symptoms (as in agoraphobia); objects or situations related to obsessions (as in obsessive-compulsive disorder); remainders of traumatic events (as in posttraumatic stress disorder); separation from home or attachment figures (as in separation anxiety disorder); or social situations (as in social anxiety disorder).

Specify if:

Code based on the phobic stimulus:

Animal (e.g., spiders, insects, dogs).

Natural environment (e.g., heights, storms, water).

Blood-injection-injury (e.g., needles, invasive medical procedures).

Situational (e.g., airplanes, elevators, enclosed places).

Other (e.g., situations that may lead to choking or vomiting; in children, e.g., loud sounds or costumed characters).

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, pp. 197–198.

Genetic or temperamental factors contribute more to the development of some anxiety disorders, whereas environmental factors are closely linked to the cause of others. Specifically, behavioral inhibition appears to be a heritable tendency and is linked with social phobia, generalized anxiety, and selective mutism. OCD and other disorders associated with OCD-like behaviors, such as Tourette syndrome and other tic disorders, tend to have high genetic risk as well (see Chapter 24.1). Environmental factors, such as parent–infant attachment and exposure to trauma, contribute more to SAD and PTSD. Parental anxiety disorder is associated with an increased risk of anxiety disorder in offspring. Differences in the size of the amygdala and hippocampus are noted in patients with anxiety symptoms.

SAD is one of the most common childhood anxiety disorders with a prevalence of 3.5-5.4%. Approximately 30% of children presenting to an outpatient anxiety disorder clinic have SAD as a primary diagnosis. Separation anxiety is developmentally normal when it begins about 10 mo of age and tapers off by 18 mo. By 3 yr of age, most children can accept the temporary absence of their mother or primary caregiver.

SAD is more common in prepubertal children, with an average age of onset of 7.5 yr. Girls are more commonly affected than boys. SAD is characterized by unrealistic and persistent worries about separation from the home or a major attachment figure. Concerns include possible harm befalling the affected child or the child's primary caregivers, reluctance to go to school or to sleep without being near the parents, persistent avoidance of being alone, nightmares involving themes of separation, numerous somatic symptoms, and complaints of subjective distress. The first clinical sign might not appear until 3rd or 4th grade, typically after a holiday or a period where the child has been home because of illness, or when the stability of the family structure has been threatened by illness, divorce, or other psychosocial stressor.

Symptoms vary depending on the child's age: Children younger than 8 yr often have associated school refusal and excessive fear that harm will come to a parent; children 9-12 yr have excessive distress when separated from a parent; and those 13-16 yr often have school refusal and physical complaints. SAD may be more likely to develop in children with lower levels of psychosocial maturity. Parents are often unable to be assertive in returning the child to school. Mothers of children with SAD often have a history of an anxiety disorder. In these cases, the pediatrician should screen for parental depression or anxiety. Often referral for parental treatment or family therapy is necessary before SAD and concomitant school refusal can be successfully treated.

Comorbidity is common in SAD. In children with comorbid tic disorders and anxiety, SAD is especially associated with tic severity. SAD is a predictor for early onset of PD. Children with SAD compared to those without SAD are 3 times more likely to develop PD in adolescence.

When a child reports recurring acute severe anxiety, antidepressant or anxiolytic medication is often necessary. Controlled studies of tricyclic antidepressants (imipramine) and benzodiazepines (clonazepam) show that these agents are not generally effective. Data support the use of cognitive-behavioral therapy (CBT) and selective serotonin reuptake inhibitors (SSRIs) (see Table 21-4 in Chapter 21). One study of children 7-17 yr of age with a primary diagnosis of SAD compared 12 wk of treatment with CBT, the SSRI sertraline, their combination, and placebo. Nearly 81% of those treated with combination therapy improved, 55% for SSRI alone, 60% for CBT. All treatments were superior to placebo (24% response rate). The SSRI was well tolerated and had few side effects; adverse events, including suicidal and homicidal ideation, did not differ between the SSRI and placebo groups and there were no attempted suicides. CBT was associated with less insomnia, fatigue, sedation, and restlessness than SSRI. Combining SSRI with CBT may be the best approach to achieving a positive response; long-term SSRI treatment can provide additional benefit. Findings from this study are consistent with a meta-analysis of published and unpublished randomized controlled trials of antidepressants for pediatric patients with SAD, social phobia, or GAD.

Childhood-onset social phobia (social anxiety disorder) is characterized by excessive anxiety in social settings (including the presence

Table 25-2	DSM-5 Diagnostic Criteria for Social Anxiety Disorder (Social Phobia)

Diagnostic Criteria

A. Marked fear or anxiety about 1 or more social situations in which the individual is exposed to possible scrutiny by others. Examples include social interactions (e.g., having a conversation, meeting unfamiliar people), being observed (e.g., eating or drinking), and performing in front of others (e.g., giving a speech).
B. The individual fears that he or she will act in a way or show anxiety symptoms that will be negatively evaluated (i.e., will be humiliating or embarrassing; will lead to rejection or offend others).
C. The social situations almost always provoke fear or anxiety.

Note: In children, the fear or anxiety may be expressed by crying, tantrums, freezing, clinging, shrinking, or failing to speak in social situations.

D. The social situations are avoided or endured with intense fear or anxiety.
E. The fear or anxiety is out of proportion to the actual threat posed by the social situation and to the sociocultural context.
F. The fear, anxiety, or avoidance is persistent, typically lasting for 6 mo or more.
G. The fear, anxiety, or avoidance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning.
H. The fear, anxiety, or avoidance is not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication) or another medical condition.
I. The fear, anxiety, or avoidance is not better explained by the symptoms of another mental disorder, such as panic disorder, body dysmorphic disorder, or autism spectrum disorder.
J. If another medical condition (e.g., Parkinson disease, obesity, disfigurement from burns or injury) is present, the anxiety or avoidance is clearly unrelated or is excessive.

Specify if:

Performance only: If the fear is restricted to speaking or performing in public.

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, pp. 202–203.

of unfamiliar peers, or unfamiliar adults) or performance situations, leading to social isolation (Table 25-2) and is associated with social scrutiny and fear of doing something embarrassing. Fear of social settings can also occur in other disorders, such as GAD. Avoidance or escape from the situation usually dissipates anxiety in **social phobia (SP),** unlike GAD, where worry persists. Children and adolescents with SP often maintain the desire for involvement with family and familiar peers. When severe, the anxiety can manifest as a panic attack.

SP is associated with a decreased quality of life, with increased likelihood of having failed at least 1 grade, and a 38% likelihood of not graduating from high school. Its onset is typically during or before adolescence and is more common in girls. A family history of SP or extreme shyness is common. Approximately 70-80% of patients with SP have at least 1 comorbid psychiatric disorder. Most shy patients do not have a SP.

Social effectiveness therapy for children (SET-C), alone or with SSRIs, is considered the treatment of choice for SP (see Table 21-4 in Chapter 21). SSRI and SET-C are superior to placebo in reducing social distress and behavioral avoidance and increasing general functioning. SET-C may be better than SSRI in reducing these symptoms. SET-C, but not SSRI, may be superior to placebo in improving social skills, decreasing anxiety in specific social interactions, and enhancing social competence. SSRIs have a maximum effect by 8 wk; SET-C provides continued improvement through 12 wk. A combination of SSRI and CBT is superior to either treatment alone in reducing severity of anxiety in children with SP and other anxiety disorders. β-Adrenergic blocking agents are used to treat SP, particularly the subtype with performance anxiety and stage fright. β-Blockers are not FDA approved for SP.

School refusal, which occurs in approximately 1-2% of children, is associated with anxiety in 40-50% of cases, depression in 50-60% of cases, and oppositional behavior in 50% of cases. Younger anxious children who refuse to attend school are more likely to have SAD, whereas older anxious children usually refuse to attend school because of SP. Somatic symptoms, especially abdominal pain and/or headaches, are common. There may be increasing tension in the parent–child relationship or other indicators of family disruption (domestic violence, divorce, or other major stressors) contributing to school refusal.

Management of school refusal typically requires parent management training and family therapy. Working with school personnel is always indicated; anxious children often require special attention from teachers, counselors, or school nurses. Parents who are coached to calmly send the child to school and to reward the child for each completed day of school are usually successful. In cases of ongoing school refusal, referral to a child and adolescent psychiatrist and psychologist is indicated. SSRI treatment may be helpful. Young children with affective symptoms have a good prognosis, whereas adolescents with more insidious onset or with significant somatic complaints have a more guarded prognosis.

Selective mutism is conceptualized as a disorder that overlaps with SP. Children with selective mutism talk almost exclusively at home, although they are reticent in other settings, such as school, daycare, or even relatives' homes. The mutism must be present for ≥1 mo. Often, 1 or more stressors, such as a new classroom or conflicts with parents or siblings, drive an already shy child to become reluctant to speak. It may be helpful to obtain history of normal language use in at least 1 situation to rule out any communication disorder (fluency disorder), neurologic disorder, or pervasive developmental disorder (autism, schizophrenia) as a cause of mutism. Fluoxetine in combination with behavioral therapy is effective for children whose school performance is severely limited by their symptoms (see Chapter 35). Other SSRIs may also be effective.

PD is a syndrome of recurrent, discrete episodes of marked fear or discomfort in which patients experience abrupt onset of physical and psychologic symptoms called *panic attacks* (Table 25-3). Physical symptoms can include palpitations, sweating, shaking, shortness of breath, dizziness, chest pain, and nausea. Children can present with acute respiratory distress but without fever, wheezing, or stridor, ruling out organic causes of the distress. The associated psychologic symptoms include fear of death, impending doom, loss of control, persistent concerns about having future attacks, and avoidance of settings where attacks have occurred (agoraphobia, Table 25-4).

PD is uncommon before adolescence, with the peak age of onset at 15-19 yr of age, occurring more often in girls. The postadolescence prevalence of PD is 1-2%. Early-onset PD and adult-onset PD do not differ in symptom severity or social functioning. Early-onset PD is associated with greater comorbidity, which can result from greater familial loading for anxiety disorders in the early-onset subtype. Children of parents with PD are much more likely to develop PD. A predisposition to react to autonomic arousal with anxiety may be a specific risk factor leading to PD. Twin studies suggest that 30-40% of the variance is attributed to genetics. The increasing rates of panic attack are also directly related to earlier sexual maturity. Cued panic attacks can be present in other anxiety disorders and differ from the uncued "out-of-the-blue" attacks in PD.

No randomized controlled trials have evaluated the effectiveness of antidepressant medication in youth with PD. Open-label studies with SSRIs appear to show effectiveness in the treatment of adolescents (see Table 21-4 in Chapter 21). CBT may also be helpful. The recovery rate is approximately 70%.

GAD occurs in children who often experience unrealistic worries about different events or activities for at least 6 mo (Table 25-5) with at least 1 somatic complaint. The diffuse nature of the anxiety symptoms differentiates it from other anxiety disorders. Worries in children with GAD commonly center around concerns about competence and performance in school and athletics. GAD often manifests with somatic symptoms including restlessness, fatigue, problems concentrating, irritability, muscle tension, and sleep disturbance. Given the somatic

Table 25-3 DSM-5 Diagnostic Criteria for Panic Disorder

A. Recurrent unexpected panic attacks. A panic attack is an abrupt surge of intense fear or intense discomfort that reaches a peak within minutes, and during which time 4 (or more) of the following symptoms occur:

Note: The abrupt surge can occur from a calm state or an anxious state.

1. Palpitations, pounding heart, or accelerated heart rate.
2. Sweating
3. Trembling or shaking.
4. Sensations of shortness of breath or smothering.
5. Feelings of choking.
6. Chest pain or discomfort.
7. Nausea or abdominal distress.
8. Feeling dizzy, unsteady, light-headed, or faint.
9. Chills or heart sensations.
10. Paresthesias (numbness or tingling sensations).
11. Derealizations (feeling or unreality) or depersonalization (being detached from one-self).
12. Fear of losing control or "going crazy."
13. Fear of dying.

Note: Culture-specific symptoms (e.g., tinnitus, neck soreness, headache, uncontrollable screaming or crying) may be seen. Such symptoms should not count as 1 of the 4 required symptoms.

B. At least 1 of the attacks has been followed by 1 mo (or more) of 1 or both of the following:
1. Persistent concern or worry about additional panic attacks or their consequences (e.g., losing control, having a heart attack, "going crazy").
2. A significant maladaptive change in behavior related to the attacks (e.g., behaviors designed to avoid having panic attacks, such as avoidance of exercise or unfamiliar situations).

C. The disturbance is not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication) or another medical condition (e.g., hyperthyroidism, cardiopulmonary disorders).

D. The disturbance is not better explained by another mental disorder (e.g., the panic attacks do not occur only in response to feared social situations, as in social anxiety disorder; in response to circumscribed phobic objects or situations, as in specific phobia; in response to obsessions, as in obsessive-compulsive disorder; or in response to reminders of traumatic events, as in posttraumatic stress disorder; or in response to separation from attachment figures, as in separation anxiety disorder).

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, pp. 208–209.

Table 25-4 DSM-5 Diagnostic Criteria for Agoraphobia

A. Marked fear or anxiety about 2 (or more) if the following 5 situations:
1. Using public transportation (e.g., automobiles, buses, trains, ships, planes).
2. Being in open spaces (e.g., parking lots, marketplaces, bridges).
3. Being in enclosed places (e.g., shops, theaters, cinemas).
4. Standing in line or being in a crowd.
5. Being outside of the home alone.

B. The individual fears or avoids these situations because of thoughts that escape might be difficult or help might not be available in the event of a developing panic-like symptoms or other incapacitating or embarrassing symptoms (e.g., fear or falling in the elderly, fear of incontinence).

C. The agoraphobic situations almost always provoke fear or anxiety.

D. The agoraphobic situations are actively avoided, require the presence of a companion, or are endured with intense fear or anxiety.

E. The fear or anxiety is out of proportion to the actual danger posed by the agoraphobic situations and to the sociocultural context.

F. The fear, anxiety, or avoidance is persistent, typically lasting for 6 mo or more.

G. The fear, anxiety, or avoidance causes clinically significant distress or impairment in social, occupational or other important area of functioning.

H. If another medical condition (e.g., inflammatory bowel disease, Parkinson disease) is present, the fear, anxiety, or avoidance is clearly excessive.

I. The fear, anxiety, or avoidance is not better explained by the symptoms or another mental disorder—for example, the symptoms are not confined to specific phobia, situational type; do not involve only social situations (as in social anxiety disorder); and are not related exclusively to obsessions (as in obsessive-compulsive disorder), reminders or traumatic events (as in posttraumatic stress disorder), or fear of separation (as in separation anxiety disorder).

Note: Agoraphobia is diagnosed irrespective of the presence of panic disorder. If an individual's presentation meets criteria for panic disorder and agoraphobia, both diagnoses should be assigned.

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, pp. 217–218.

symptoms characteristic of GAD, the differential diagnosis must consider other medical causes. Excessive use of caffeine or other stimulants in adolescence is common and should be determined with a careful history. When the history or physical exam is suggestive, the pediatrician should rule out hyperthyroidism, hypoglycemia, lupus, and pheochromocytoma.

Children with GAD are markedly self-conscious and perfectionistic and struggle with more intense distress than is evident to parents or others around them. They often have other anxiety disorders, such as simple phobia and PD. Onset may be gradual or sudden, although GAD does not often become manifest until puberty. Boys and girls are equally affected before puberty, when GAD becomes more prevalent in girls. The prevalence of GAD ranges from 2.5-6% of children. Hypermetabolism in frontal precortical area and increased blood flow in the right dorsolateral prefrontal cortex may be present.

Children with GAD are good candidates for CBT, an SSRI, or their combination (see Table 21-4 in Chapter 21). Buspirone may be used as an adjunct to SSRI therapy. Combination of CBT and SSRI often results in a superior response in pediatric patients with anxiety disorders, including GAD. The recovery rate is approximately 80%.

It is important to distinguish children with GAD from those who present with specific repetitive thoughts that invade consciousness **(obsessions)** or repetitive rituals or movements that are driven by anxiety **(compulsions)**. The most common obsessions are concerned with bodily wastes and secretions, the fear that something calamitous will happen, or the need for sameness. The most common compulsions are hand washing, continual checking of locks, and touching. At times of stress (bedtime, preparing for school), some children touch certain objects, say certain words, or wash their hands repeatedly. OCD is diagnosed when the thoughts or rituals cause distress, consume time, or interfere with occupational or social functioning (Table 25-6). In the DSM-5, OCD and related disorders (such as trichotillomania, excoriation, body dysmorphic disorder, and hoarding) are listed separately and are no longer included under anxiety disorders.

OCD is a chronically disabling illness characterized by repetitive, ritualistic behaviors over which the patient has little or no control. OCD has a lifetime prevalence of 1-3% worldwide, and as many as 80% of all cases have their onset in childhood and adolescence. Common obsessions include contamination (35%) and thoughts of harming loved ones or oneself (30%). Washing and cleaning compulsions are common in children (75%), as are checking (40%) and straightening (35%). Many children are observed to have visuospatial irregularities, memory problems, and attention deficits, causing academic problems not explained by OCD symptoms alone.

Table 25-5 DSM-5 Diagnostic Criteria for Generalized Anxiety Disorder

A. Excessive anxiety and worry (apprehensive expectation), occurring more days than not for at least 6 mo, about a number of events or activities (such as work or school performance).
B. The individual finds it difficult to control the worry.
C. The anxiety and worry are associated with 3 (or more) of the following 6 symptoms (with at least some symptoms having been present for more days than not for the past 6 mo):
Note: Only 1 item is required in children.
1. Restlessness or feeling keyed up or on edge.
2. Being easily fatigued.
3. Difficulty concentrating or mind going blank.
4. Irritability.
5. Muscle tension.
6. Sleep disturbance (difficulty falling or staying asleep, or restless, unsatisfying sleep).

D. The anxiety, worry or physical symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.
E. The disturbance is not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication) or other medical condition (e.g., hyperthyroidism).
F. The disturbance is not better explained by another mental disorder (e.g., anxiety or worry about having panic attacks in panic disorder, negative evaluation in social anxiety disorder [social phobia], contamination or other obsessions in obsessive-compulsive disorder, separation from attachment figures in separation anxiety disorder, remainders of traumatic events in posttraumatic stress disorder, gaining weight in anorexia nervosa, physical complaints in somatic symptom disorder, perceived appearance flaws in body dysmorphic disorder, having a serious illness in illness anxiety disorder, or the content of delusional beliefs in schizophrenia or delusional disorder).

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, p. 222.

The Children's Yale-Brown Obsessive-Compulsive Scale (C-YBOCS) and the Anxiety Disorders Interview Schedule for Children (ADIS-C) are reliable and valid methods for identifying children with OCD. The C-YBOCS is helpful in following the progression of symptoms with treatment. The Leyton Obsessional Inventory (LOI) is a self-report measure of OCD symptoms that is quite sensitive. Patients with OCD have consistently identified abnormalities in the frontostriatal-thalamic circuitry associated with severity of illness and treatment response. Comorbidity is common in OCD, with 30% of patients having comorbid tic disorders, 26% having comorbid major depression, and 24% having comorbid developmental disorders.

Consensus guidelines recommend that children and adolescents with OCD begin treatment with either CBT alone or CBT in combination with SSRI, when symptoms are moderate to severe (YBOCS >21). In OCD patients with comorbid tics, SSRIs are no more effective than placebo, and combination of CBT and SSRI is superior to CBT; CBT alone is superior to placebo. Pediatric OCD patients with comorbid tics should begin treatment with CBT alone or the combination of CBT and SSRI. Pediatric patients with OCD who have a family history of OCD may be significantly less responsive to CBT alone than patients without a family history of OCD.

There are 4 FDA-approved medications for pediatric OCD: fluoxetine, sertraline, fluvoxamine, and clomipramine. Clomipramine, a heterocyclic antidepressant and nonselective serotonin and norepinephrine reuptake inhibitor, is only indicated when a patient has failed 2 or more SSRI trials. There may be a role for glutamate-modulating medications in the treatment of OCD. The glutamate inhibitor riluzole (Rilutek) is FDA-approved for amyotrophic lateral sclerosis (see Chapter 612.3) and has a good safety record. The most common adverse event with riluzole is transient increase in liver transaminases. Riluzole in children with treatment-resistant OCD may be beneficial and is well tolerated. Other glutamate-modulating agents, such as memantine, *N*-acetyl-cysteine, and D-cycloserine, have been used with some success in patients with OCD. Referral of patients with OCD to a mental health professional is always indicated.

Table 25-6 DSM-5 Diagnostic Criteria for Obsessive-Compulsive Disorder

A. Presence of obsessions, compulsions, or both:
Obsessions are defined by (1) and (2):
1. Recurrent and persistent thoughts, urges, or images that are experienced, at some time during the disturbance, as intrusive and unwanted, and that in most individuals cause marked anxiety or distress.
2. The individual attempts to ignore or suppress such thoughts, urges or images, or to neutralize them with some other thought or action (i.e., by performing a compulsion).

Compulsions are defined by (1) and (2):
1. Repetitive behaviors (e.g., hand washing, ordering, checking) or mental acts (e.g., praying, counting, repeating words silently) that the individual feels driven to perform in response to an obsession or according to rules that must be applied rigidly.
2. The behaviors or mental acts are aimed at preventing or reducing anxiety or distress, or preventing some dreaded event or situation; however, these behaviors or mental acts are not connected in a realistic way with what they are designed to neutralize or prevent, or are clearly excessive.

B. The obsessions or compulsions are time-consuming (e.g., take more than 1 hr per day) or cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.
C. The obsessive-compulsive symptoms are not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication) or another medical condition.
D. The disturbance is not better explained by the symptoms of another mental disorder (e.g., excessive worries, as in generalized anxiety disorder; preoccupation with appearance, as in body dysmorphic disorder; difficulty discarding or parting with possessions, as in hoarding disorder; hair pulling, as in trichotillomania [hair-pulling disorder]; skin picking, as in excoriation [skin-picking] disorder; stereotypies, as in stereotypic movement disorder; ritualized eating disorder, as in eating disorders; preoccupation with substances or gambling, as in substance-related and addictive disorders; preoccupation with having an illness, as in illness anxiety disorder; sexual urges or fantasies, as in paraphilic disorders; impulses, as in disruptive, impulse-control and conduct disorders; guilty ruminations, as in schizophrenia spectrum and other psychotic disorders; or repetitive patterns of behavior, as in autism spectrum disorder).

Specify if:
With good or fair insight: The individual recognizes that obsessive-compulsive disorder beliefs are definitely or probably not true or that they may or may not be true.
With poor insight: The individual thinks obsessive-compulsive disorder beliefs are probably true.
With absent insight/delusional beliefs: The individual is completely convinced that obsessive-compulsive disorder beliefs are true.
Specify if:
Tic-related: The individual has a current or past history of a tic disorder.

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, p. 237.

In 10% of children with OCD, symptoms are triggered or exacerbated by group A β-hemolytic streptococcal infection (see Chapter 183). Group A β-hemolytic streptococcal bacteria trigger antineuronal antibodies that cross-react with basal ganglia neural tissue in genetically susceptible hosts, leading to swelling of this region and resultant obsessions and compulsions. This subtype of OCD, called **pediatric autoimmune neuropsychiatric disorder associated with streptococcal infection (PANDAS),** is characterized by sudden and dramatic onset or exacerbation of OCD or tic symptoms, associated neurologic findings, and a recent streptococcal infection. Increased

antibody titers of antistreptolysin O and antideoxyribonuclease B correlates with increased basal ganglia volumes. Plasmapheresis is effective in reducing OCD symptoms in some patients with PANDAS and also decreasing enlarged basal ganglia volume. OCD has also followed episodes of acute disseminated encephalomyelitis (see Chapter 600.3) The pediatrician should be aware of the infectious cause of some cases of tic disorders, attention-deficit disorder, and OCD and follow management guidelines (see Chapter 24).

Children with **phobias** avoid specific objects or situations that reliably trigger physiologic arousal (e.g., dogs or spiders) (see Table 25-1). The fear is excessive and unreasonable and can be cued by the presence or anticipation of the feared trigger, with anxiety symptoms occurring immediately. Neither obsessions nor compulsions are associated with the fear response; phobias only rarely interfere with social, educational, or interpersonal functioning. Assault by a relative and verbal aggression between parents can influence the onset of specific phobias. The parents of phobic children should remain calm in the face of the child's anxiety or panic. Parents who become anxious themselves may reinforce their children's anxiety, and the pediatrician can usefully interrupt this cycle by calmly noting that phobias are not unusual and rarely cause impairment. The prevalence of specific phobias in childhood is 0.5-2%.

Systematic desensitization is a form of behavior therapy that gradually exposes the patient to the fear-inducing situation or object, while simultaneously teaching relaxation techniques for anxiety management. Successful repeated exposure leads to extinguishing anxiety for that stimulus. When phobias are particularly severe, SSRIs can be used with behavioral intervention. Low-dose SSRI treatment may be especially effective for some children with severe, refractory choking phobia.

PTSD (see Chapter 39) is typically precipitated by an extreme stressor. PTSD is an anxiety disorder resulting from the long- and short-term effects of trauma that cause behavioral and physiologic sequelae in toddlers, children, and adolescents (Table 25-7). Another

Table 25-7 DSM-5 Diagnostic Criteria for Posttraumatic Stress Disorder

POSTTRAUMATIC STRESS DISORDER

Note: The following criteria apply to adults, adolescents, and children older than 6 yr. For children 6 yr and younger, see corresponding criteria below.

A. Exposure to actual or threatened death, serious injury, or sexual violence in 1 (or more) of the following ways:
   1. Directly experiencing the traumatic event(s).
   2. Witnessing, in person, the event(s) as it occurred to others.
   3. Learning that the traumatic event(s) occurred to a close family member or close friend. In cases of actual or threatened death of a family member or friend, the event(s) must have been violent or accidental.
   4. Experiencing repeated or extreme exposure to aversive details of the traumatic event(s) (e.g., 1st responders collecting human remains; police officers repeatedly exposed to details of child abuse).

Note: Criterion A4 does not apply to exposure through electronic media, television, movies or pictures, unless this exposure is work related.

B. Presence of 1 (or more) of the following intrusion symptoms associated with the traumatic event(s), beginning after the traumatic event(s) occurred:
   1. Recurrent, involuntary, and intrusive distressing memories of the traumatic event(s).

Note: In children older than 6 yr, repetitive play may occur in which themes or aspects of the traumatic event(s) are expressed.

   2. Recurrent distressing dreams in which the content and/or affect of the dream are related to the traumatic event(s).

Note: In children, there may be frightening dreams without recognizable content.

   3. Dissociative reactions (e.g., flashbacks) in which the individual feels or acts as if the traumatic event(s) were recurring. (Such reactions may occur on a continuum, with the more extreme expression being a complete loss or awareness of present surroundings.)

Note: In children, trauma-specific reenactment may occur in play.

   4. Intense or prolonged psychological distress at exposure to internal or external cues that symbolize or resemble an aspect of the traumatic event(s).
   5. Marked physiologic reactions to internal or external cues that symbolize or resemble an aspect of the traumatic event(s).

C. Persistent avoidance of stimuli associated with the traumatic event(s), beginning after the traumatic event(s) occurred, as evidenced by 1 or both of the following:
   1. Avoidance of or efforts to avoid distressing memories, thoughts or feelings about or closely associated with the traumatic event(s).
   2. Avoidance of or efforts to avoid external reminders (people, places, conversations, activities, objects, situations) that around distressing memories, thoughts or feelings about or closely associated with the traumatic event(s).

D. Negative alterations in cognitions and mood associated with the traumatic event(s), beginning or worsening after the traumatic event(s) occurred, as evidenced by 2 (or more) of the following:
   1. Inability to remember an important aspect of the traumatic event(s) (typically due to dissociative amnesia and not to other factors such as head injury, alcohol, or drugs).
   2. Persistent and exaggerated negative beliefs or expectations about oneself, others, or the world (e.g., "I am bad," "No one can be trusted," "The world is completely dangerous," "My whole nervous system is permanently ruined").
   3. Persistent, distorted cognitions about the cause or consequences of the traumatic event(s) that lead the individual to blame himself/herself or others.
   4. Persistent negative emotional state (e.g., fear, horror, anger, guilt, or shame).
   5. Markedly diminished interest or participation in significant activities.
   6. Feelings of detachment or estrangement from others.
   7. Persistent inability to experience positive emotions (e.g., inability to experience happiness, satisfaction, or loving feelings).

E. Marked alterations in arousal and reactivity associated with the traumatic event(s), beginning or worsening after the traumatic event(s) occurred, as evidenced by 2 (or more) of the following:
   1. Irritable behavior and angry outbursts (with little or no provocation) typically expressed by verbal or physical aggression toward people or objects.
   2. Reckless or self-destructive behavior.
   3. Hypervigilance.
   4. Exaggerated startle response.
   5. Problems with concentration.
   6. Sleep disturbance (e.g., difficulty falling or staying asleep or restless sleep).

F. Duration of the disturbance (Criteria B, C, D, and E) is more than 1 mo.

G. The disturbance causes clinically significant distress or impairment in social, occupational or other important areas of functioning.

H. The disturbance is not attributable to the physiologic effects of a substance (e.g., medication, alcohol) or another medical condition.

Continued

Table 25-7 DSM-5 Diagnostic Criteria for Posttraumatic Stress Disorder—cont'd

Specify whether

With dissociative symptoms: The individual's symptoms meet the criteria for posttraumatic stress disorder, and in addition, in response to the stressor, the individual experiences persistent or recurrent symptoms of either of the following:

1. **Depersonalization:** Persistent or recurrent experiences of feeling detached from, and as if one were an outside observer of, one's mental processes or body (e.g., feeling as though one were in a dream; feeling a sense of unreality of self or body or of time moving slowly).
2. **Derealization:** Persistent or recurrent experiences of unreality of surroundings (e.g., the world around the individual is experienced as unreal, dreamlike, distant, or distorted).

Note: to use this subtype, the dissociative symptoms must not be attributable to the physiologic effects of a substance (e.g., blackouts, behavior during alcohol intoxication) or another medical condition (e.g., complex partial seizures).

Specify if:

With delayed expression: If the full diagnostic criteria are not met until at least 6 mo after the event (although the onset and expression of some symptoms may be immediate).

POSTTRAUMATIC STRESS DISORDER FOR CHILDREN 6 YR AND YOUNGER

A. In children 6 yr and younger, exposure to actual or threatened death, serious injury, or sexual violence in 1 (or more) of the following ways:
   1. Directly experiencing the traumatic event(s).
   2. Witnessing, in person, the event(s) as it occurred to others, especially primary caregivers.

Note: Witnessing does not include events that are only in electronic media, television, movies, or pictures.

   3. Learning that the traumatic event(s) occurred to a parent or caregiving figure.

B. Presence of 1 (or more) of the following intrusion symptoms associated with the traumatic event(s), beginning after the traumatic event(s) occurred:
   1. Recurrent, involuntary, and intrusive distressing memories of the traumatic event(s).

Note: Spontaneous and intrusive memories may not necessarily appear distressing and may be expressed as play reenactment.

   2. Recurrent distressing dreams in which the content and/or affect of the dream is related to the traumatic event(s).

Note: It may not be possible to ascertain that the frightening content is related to the traumatic event.

   3. Dissociative reactions (e.g., flashbacks) in which the child feels or acts as if the traumatic event(s) were recurring. (Such reactions may occur on a continuum, with the most extreme expression being a complete loss of awareness of present surroundings.) Such trauma-specific reenactment may occur in play.
   4. Intense or prolonged psychological distress at exposure to internal or external cues that symbolize or resemble an aspect of the traumatic event(s).

C. One (or more) of the following symptoms, representing either persistent avoidance of stimuli associated with the traumatic event(s) or negative alterations in cognitions and mood associated with the traumatic event(s), must be present, beginning after the event(s) or worsening after the event(s):

Persistent Avoidance of Stimuli

   1. Avoidance of or efforts to avoid activities, places, or physical reminders that arouse recollections or the traumatic event(s).
   2. Avoidance of or efforts to avoid people, conversations, or interpersonal situations that around recollections of the traumatic event(s).

Negative Alterations in Cognitions

   3. Substantially increased frequency of negative emotional states (e.g., fear, guilt, sadness, shame, confusion).
   4. Markedly diminished interest or participation in significant activities, including constriction of play.
   5. Socially withdrawn behavior.
   6. Persistent reduction in expression of positive emotions.

D. Alterations in arousal and reactivity associated with the traumatic event(s), beginning or worsening after the traumatic event(s) occurred, as evidenced by 2 (or more) of the following:
   1. Irritable behavior and angry outbursts (with little or no provocation), typically expressed as verbal and physical aggression toward people or objects (including extreme temper tantrums).
   2. Hypervigilance.
   3. Exaggerated startle response.
   4. Problems with concentration.
   5. Sleep disturbance (e.g., difficulty falling asleep or staying asleep or restless sleep).

E. The duration of the disturbance is more than 1 mo.

F. The disturbance causes clinically significant distress or impairment in relationships with parents, siblings, peers, or other caregivers or with school behavior.

G. The disturbance is not attributable to the physiologic effects of a substance (e.g., medication or alcohol) or another medical condition.

Specify whether:

With dissociative symptoms: The individual's symptoms meet the criteria for posttraumatic stress disorder, and the individual experiences persistent or recurrent symptoms of either of the following:

1. **Depersonalization:** Persistent or recurrent experiences of feeling detached from, and as if one were an outside observer of, one's mental processes or body (e.g., feeling as though one were in a dream; feeling a sense of unreality of self or body or of time moving slowly).
2. **Derealization:** Persistent or recurrent experiences of unreality of surroundings (e.g., the world around the individual is experienced as unreal, dreamlike, distant, or distorted).

Note: to use this subtype, the dissociative symptoms must not be attributable to the physiologic effects of a substance (e.g., blackouts, behavior during alcohol intoxication) or another medical condition (e.g., complex partial seizures).

Specify if:

With delayed expression: If the full diagnostic criteria are not met until at least 6 mo after the event (although the onset and expression of some symptoms may be immediate).

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, pp. 271–274.

diagnostic category, **acute stress disorder**, reflects the fact that traumatic events often cause acute symptoms that may or may not resolve. Previous trauma exposure, a history of other psychopathology, and symptoms of PTSD in parents predict childhood-onset PTSD. Many adolescent and adult psychopathologic conditions, such as conduct disorder, depression, and some personality disorders, might relate to previous trauma. PTSD is also linked to mood disorders and disruptive behavior. Separation anxiety is common in children with PTSD. The lifetime prevalence of PTSD by age 18 yr is approximately 6%. Up to 40% show symptoms, but do not fulfill the diagnostic criteria.

Events that pose physical injury, harm, or death to the child, to the child's caregiver, or to others close to the child and that produce considerable stress, fear, and/or helplessness are required to make the diagnosis of PTSD. Three clusters of symptoms are also essential for diagnosis: reexperiencing, avoidance, and hyperarousal. Persistent reexperiencing of the stressor through intrusive recollections, nightmares, and reenactment in play are typical responses in children. Persistent avoidance of reminders and numbing of emotional responsiveness, such as isolation, amnesia, and avoidance, constitute the second cluster of behaviors. Symptoms of hyperarousal, such as hypervigilance, poor concentration, extreme startle responses, agitation, and sleep problems, complete the symptom profile of PTSD. Occasionally, children regress in some of their developmental milestones after a traumatic event. Avoidance symptoms are commonly observable in younger children, whereas older children may be more able to describe reexperiencing and hyperarousal symptoms. Repetitive play involving the event, psychosomatic symptoms, and nightmares may also be observed.

Initial interventions after a trauma should focus on reunification with a parent and attending to the child's physical needs in a safe place. Aggressive treatment of pain might decrease the likelihood of PTSD, and facilitating a return to comforting routines, including regular sleep, is indicated. Long-term treatment may include individual, group, school-based, or family therapy, as well as pharmacotherapy, in selected cases. Individual treatment involves transforming the child's concept of himself or herself as victim to that of survivor and can occur through play therapy, psychodynamic therapy, or CBT. Group work is also helpful for identifying which children might need more intensive assistance. Goals of family work include helping the child establish a sense of security, validating the child's emotions, and anticipating situations when the child will need more support from the family. Clonidine or guanfacine may be helpful for sleep disturbance, persistent arousal, and exaggerated startle response. Recent randomized controlled trials in children and adolescents with PTSD did not find a significant difference between SSRI and placebo. SSRIs may be considered in pediatric patients with PTSD who have comorbid conditions responsive to SSRIs, for example, depression, affective numbing, and anxiety (see Table 21.4 in Chapter 21). As for many other anxiety disorders, CBT is the psychotherapeutic intervention with the most empiric support.

ANXIETY ASSOCIATED WITH MEDICAL CONDITIONS

It is prudent to rule out organic conditions such as hyperthyroidism, caffeinism (carbonated beverages), hypoglycemia, central nervous system disorders (delirium, encephalopathy, brain tumors), migraine, asthma, lead poisoning, cardiac arrhythmias, and, rarely, pulmonary embolism, hyperparathyroidism, systemic lupus erythematosus, anaphylaxis, porphyria or pheochromocytoma, before making a diagnosis of an anxiety disorder. Some prescription drugs with side effects that can mimic anxiety include antiasthmatic agents, steroids, sympathomimetics, SSRIs (initiation), anticholinergic agents, and antipsychotics. Nonprescription drugs causing anxiety include diet pills, antihistamines, stimulate drugs of abuse, drug withdrawal, and cold medicines.

Chronic illness is also an underlying cause of anxiety. Children are not often emotionally and cognitively competent to understand the implications of a serious and prolonged illness. In addition to the physiologic implications of illness they must also attend to the hospitalizations, procedures and medications that permeate their everyday schedule. This experience affects their schooling, friendships, activities, and dynamics of the nuclear family including the experiences of their well siblings.

School issues surrounding both prolonged absences and school re-entry following a medical condition can cause, or reinforce and escalate existing anxiety. School is a foundation not only for learning, but it is central to children's social experiences and feelings of normalcy. It is often impeded and stunted by illness. Academic struggles can result from missing classes, medication and emotional status. Children with chronic conditions are also socially disadvantaged with friendship networks hampered by unstable attendance or by social rejection for being different. Consulting with the school psychologist can be beneficial in preparing teachers and classmates before the child returns to school. An agreement between the student and school staff should be implemented outlining a plan for taking medication, needing rest or consulting on other needs. If the child and family wish, an informational meeting with students and teachers can normalize the situation. Explaining the condition makes it less scary for children who catastrophize or worry about contagion. Classmates and teachers are a natural and accessible resource and can be an incredible support and community. Medication may also be warranted to supplement social supports.

The experiences of the siblings of children with chronic illness are often forgotten with familial resources focused on medical and financial consequences, and the emotional and physical functioning of the ill child. It is not uncommon for the siblings of ill children to experience depression and anxiety as well. Assessing their social support systems, communication opportunities with parents and emotional outlets are critical to maintaining healthy functioning. Maintaining a redefined schedule of after-school activities and social engagements are helpful in allowing siblings to continue in school.

SAFETY AND EFFICACY CONCERNS ABOUT SSRIS

No empiric evidence suggests the superiority of one SSRI over another. Data are limited as far as combining medications are concerned. SSRIs are usually well tolerated by most children and adolescents. The FDA issued a black box warning of increased agitation and suicidality among adolescents and children on these medications. This warning was based on review of studies in children and adolescents with major depression and not anxiety disorders. Close monitoring is always warranted.

Chapter 26

Mood Disorders

Heather J. Walter, Natalija Bogdanovic, Lovern R. Moseley, and David R. DeMaso

Mood disorders are interrelated sets of psychiatric symptoms characterized by a core deficit in emotional self-regulation. Classically, the mood disorders have been divided into depressive and bipolar disorders, representing the 2 emotional polarities (dysphoric ["low"] and euphoric ["high"] mood).

26.1 Major and Other Depressive Disorders

Heather J. Walter, Lovern R. Moseley, and David R. DeMaso

The depressive disorders include major depressive, persistent depressive, disruptive mood dysregulation, other specified/unspecified

Table 26-1 DSM-5 Diagnostic Criteria for Major Depressive Episode

A. Five (or more) of the following symptoms have been present during the same 2 wk period and represent a change from previous functioning; at least 1 of the symptoms is either (1) depressed mood or (2) loss of interest or pleasure.
  1. Depressed most of the day, nearly every day, as indicated by either subjective report (e.g., feels sad, empty, hopeless) or observation made by others (e.g., appears tearful). **Note:** In children and adolescents, can be irritable mood.
  2. Markedly diminished interest or pleasure in all, or almost all, activities most of the day, nearly every day (as indicated by either subjective account or observation).
  3. Significant weight loss when not dieting or weight gain (e.g., a change of more than 5% of body weight in a month), or decrease or increase in appetite nearly every day. **Note:** In children, consider failure to make expected weight gain.
  4. Insomnia or hypersomnia nearly every day.
  5. Psychomotor agitation or retardation nearly every day (observable by others, not merely subjective feelings of restlessness or being slowed down).
  6. Fatigue or loss of energy nearly every day.
  7. Feelings of worthlessness or excessive or inappropriate guilt (which may be delusional) nearly every day (not merely self-reproach or guilt about being sick).
  8. Diminished ability to think or concentrate, or indecisiveness, nearly every day (either by subjective account or as observed by others).
  9. Recurrent thoughts of death (not just fear of dying), recurrent suicidal ideation without a specific plan, or a suicide attempt or a specific plan for committing suicide.

B. The symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.
C. The episode is not attributable to the physiological effects of a substance or to another medical condition.

Note: Criteria A-C represent a major depressive episode.

D. The occurrence of the major depressive episode is not better explained by schizoaffective disorder, schizophrenia, schizophreniform disorder, delusional disorder, or other specified and unspecified schizophrenia spectrum and other psychotic disorders.
E. There has never been a manic episode or a hypomanic episode.

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, pp. 125–126.

Table 26-2 DSM-5 Diagnostic Criteria for Persistent Depressive Disorder

A. Depressed mood for most of the day, for more days than not, as indicated either by subjective account or observation by others, for at least 2 yr.

Note: In children and adolescents, mood can be irritable and duration must be at least 1 yr.

B. Presence, while depressed, of 2 (or more) of the following:
  1. Poor appetite or overeating.
  2. Insomnia or hypersomnia.
  3. Low energy or fatigue.
  4. Low self-esteem.
  5. Poor concentration or difficulty making decisions.
  6. Feelings of hopelessness.

C. During the 2 yr period (1 yr for children or adolescents) of the disturbance, the individual has never been without the symptoms in Criteria A and B for more than 2 mo at a time.
D. Criteria for a major depressive disorder may be continuously present for 2 yr.
E. There has never been a manic episode or a hypomanic episode, and criteria have never been met for cyclothymic disorder.
F. The disturbance is not better explained by a persistent schizoaffective disorder, schizophrenia, delusional disorder, or other specified or unspecified schizophrenia spectrum and other psychotic disorder.
G. The symptoms are not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication) or another medical condition (e.g., hypothyroidism).
H. The symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.

Note: Because the criteria for a major depressive episode include 4 symptoms that are absent from the symptom list for persistent depressive disorder (dysthymia), a very limited number of individuals will have depressive symptoms that have persisted longer than 2 yr but will not meet criteria for persistent depressive disorder. If full criteria for a major depressive episode have been met at some point during the current episode of illness, they should be given a diagnosis of major depressive disorder. Otherwise, a diagnosis of other specified depressive disorder or unspecified depressive disorder is warranted.

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, pp. 168–169.

depressive, premenstrual dysphoric, and substance/medication-induced disorders, as well as depressive disorder caused by another medical condition.

DESCRIPTION

Major depressive disorder (**MDD**) is characterized by a distinct period of at least 2 wk (an episode; Table 26-1) in which there is a depressed or irritable mood and/or loss of interest or pleasure in almost all activities that is present for most of the day, nearly every day. Major depression is associated with characteristic vegetative and cognitive symptoms, including disturbances in appetite, sleep, energy, and activity level; impaired concentration; thoughts of worthlessness or guilt; and suicidal thoughts or actions. Major depression is considered to be mild if few or no, symptoms in excess of those required to make the diagnosis are present, and the symptoms are mildly distressing and manageable and result in minor functional impairment. Major depression is considered to be severe if symptoms substantially in excess of those required to make the diagnosis are present, and the symptoms are highly distressing and unmanageable and markedly impair function. Moderate major depression is intermediate in severity between mild and severe.

Persistent depressive disorder (dysthymia) (Table 26-2) is characterized by depressed or irritable mood for more days than not, for at least 1 yr (in children/adolescents). As with major depression, this chronic form of depression is associated with characteristic vegetative and cognitive symptoms; however, the cognitive symptoms of persistent depression are less severe (e.g., low self-esteem rather than worthlessness, hopelessness rather than suicidality). In the same way as major depression, persistent depressive disorder is characterized as mild, moderate, or severe.

Overall, the clinical presentation of major and persistent depressive disorders in children and adolescents is similar to that in adults. The prominence of the symptoms can change with age: irritability and somatic complaints may be more common in children, and energy, activity level, appetite, and sleep disturbances may be more common in adolescents. Because of the cognitive and linguistic immaturities of young children, symptoms of depression in that age group may be more likely to be observed than self-reported.

The core feature of ***disruptive mood dysregulation disorder*** (**DMDD**) (Table 26-3) is severe, persistent irritability evident for at least 12 mo in multiple settings (at home, at school, with peers). This irritability is characterized by frequent and severe temper outbursts (verbal and/or physical) and a persistently irritable or angry mood that is present for most of the day, nearly every day. This diagnosis is intended to more accurately characterize the extreme irritability heretofore considered by some investigators to be a developmental presentation of bipolar disorder (see Chapter 26.2), and to distinguish extreme irritability from the milder presentations characteristic of oppositional defiant and intermittent explosive disorders (see Chapter 29).

Table 26-3 DSM-5 Diagnostic Criteria for Disruptive Mood Dysregulation Disorder

A. Severe recurrent temper outbursts manifested verbally (e.g., verbal rages) and/or behaviorally (e.g., physical aggression toward people or property) that are grossly out of proportion in intensity or duration to the situation or provocation.
B. The temper outbursts are inconsistent with developmental level.
C. The temper outbursts occur, on average, 3 or more times per week.
D. The mood between temper outbursts is persistently irritable or angry most of the day, nearly every day, and is observable by others (e.g., parents, teachers, peers).
E. Criteria A-D have been present for 12 or more months. Throughout that time, the individual has not had a period lasting 3 or more consecutive months without all of the symptoms in Criteria A-D.
F. Criteria A and D are present in at least 2 of 3 settings (i.e., at home, at school, with peers) and are severe in at least 1 of these.
G. The diagnosis should not be made for the first time before age 6 yr or after age 18 yr.
H. By history or observation, the age at onset of Criteria A-E is before 10 yr.
I. There has never been a distinct period lasting more than 1 day during which the full symptom criteria, except duration, for a manic or hypomanic episode have been met.

Note: Developmentally appropriate mood elevation, such as occurs in the context of a highly positive event or its anticipation, should not be considered as a symptom of mania or hypomania.

J. The behaviors do not occur exclusively during an episode of major depressive disorder and are not better explained by another mental disorder (e.g., autism spectrum disorder, posttraumatic stress disorder, separation anxiety disorder, persistent depressive disorder [dysthymia]).

Note: The diagnosis cannot coexist with oppositional defiant disorder, intermittent explosive disorder, or bipolar disorder, though it can coexist with others, including major depressive disorder, attention-deficit/hyperactivity disorder, conduct disorder, and substance use disorders. Individuals whose symptoms meet criteria for both disruptive mood dysregulation disorder and oppositional defiant disorder should only be given the diagnosis of disruptive mood dysregulation disorder. If an individual has ever experienced a manic or hypomanic episode, the diagnosis of disruptive mood dysregulation disorder should not be assigned.

K. The symptoms are not attributable to the physiologic effects of a substance or to another medical or neurologic condition.

From the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, p. 156.

Other specified/unspecified depressive disorder (subsyndromal depressive disorder) applies to presentations in which symptoms characteristic of a depressive disorder are present and cause clinically significant distress or functional impairment, but do not meet the full criteria for any of the disorders in this diagnostic class.

EPIDEMIOLOGY

The overall prevalence of parent-reported diagnosis of depressive disorder in the United States (excluding DMDD) among 3-17 yr old children is ~2.1% (current) and ~3.9% (ever); the prevalence rate increases to ~12.8% (lifetime) for 12-17 yr olds. The male : female ratio (excluding DMDD) approximates 1 : 1 during childhood and beginning in early adolescence rises to 1 : 1.5-3.0 in adulthood.

Based upon rates of chronic and severe persistent irritability, which is the core feature of DMDD, the overall 6 mo to 1 yr prevalence has been estimated to fall within the 2-5% range. In 3 community samples, the 3 mo prevalence rate of DMDD ranged from 0.8-3.3%, with the highest rates occurring in preschoolers. Approximately 5-10% of children and adolescents are estimated to have subsyndromal (unspecified) depression.

CLINICAL COURSE

Major depression may first appear at any age, but the likelihood of onset increases markedly with puberty. Incidence appears to peak in the 20s. The median duration of a major depressive episode approximates 5-8 mo for clinically referred youth and 3-6 mo for community samples. The course is quite variable in that some individuals rarely or never experience remission, whereas others experience many years with few or no symptoms between episodes. Persistent depressive disorder often has an early and insidious onset, and by definition, a chronic course (average untreated duration in both clinical and community samples: 3.5 yr).

Prepubertal depressive disorders exhibit more heterotypic than homotypic continuity; depressed children appear to be more likely to develop nondepressive psychiatric disorders in adulthood than depressive disorders. Adolescents exhibit greater homotypic continuity, with the probability of recurrence of depression reaching 50%-70% after 5 yr. The persistence of even mild depressive symptoms during remission is a powerful predictor of recurrence; other negative prognostic factors include more severe symptoms, longer time to remission, history of maltreatment, and comorbid psychiatric disorders. Up to 20% of depressed adolescents develop a bipolar disorder; the risk is higher among adolescents who have a high family loading for bipolar disorder, who have psychotic depression, or who have had pharmacologically induced mania.

DIFFERENTIAL DIAGNOSIS

A number of psychiatric disorders, general medical conditions, and medications can generate symptoms of depression or irritability and must be distinguished from the depressive disorders. The psychiatric disorders include autism spectrum (see Chapter 30), attention-deficit/hyperactivity (ADHD; see Chapter 33), bipolar, anxiety (see Chapter 25), trauma- and stressor-related, disruptive/impulse control/conduct, and substance-related disorders. Medical conditions include neurologic disorders, endocrine disorders, infectious diseases, tumors, anemia, uremia, failure to thrive, chronic fatigue disorder, and pain disorder. Medications include narcotics, chemotherapy agents, β-blockers, corticosteroids, and contraceptives. The diagnosis of a depressive disorder should be made after these other explanations for the observed symptoms have been ruled out.

COMORBIDITY

Major and persistent depressive disorders often co-occur with other psychiatric disorders. Depending on the setting and source of referral, 40-90% of youths with a depressive disorder have other psychiatric disorders, and up to 50% have 2 or more comorbid diagnoses. The most common comorbid diagnosis is an anxiety disorder and as such may reflect a common diathesis; other common comorbidities include ADHD and disruptive behavior, eating, and substance use disorders. The development of depressive disorders can both lead and follow the development of the comorbid disorders.

Preliminary data suggests the co-occurrence of DMDD with other psychiatric disorders, including other depressive disorders, ADHD, conduct disorder, and substance use disorders, from 60-90% of the time. Because the symptoms of DMDD overlap in part with symptoms of bipolar disorder (see Chapter 26.2), oppositional defiant disorder (see Chapter 29), and intermittent explosive disorder (see Chapter 29), by *Diagnostic Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) convention hierarchical diagnostic rules apply (i.e., bipolar disorder takes precedence over DMDD if a manic/hypomanic episode has ever occurred; DMDD takes precedence over oppositional defiant disorder and intermittent explosive disorder if full criteria for DMDD are met).

SEQUELAE

Approximately 60% of youths with MDD report thinking about suicide, and 30% actually attempt suicide. The risk of suicidal behavior increases if there is a history of suicide attempts, exposure to adverse psychosocial circumstances, a family history of suicidal behavior, or comorbid psychiatric disorders. Youths with depressive disorders are also at high

risk of substance abuse, impaired family and peer relationships, early pregnancy, legal problems, educational and occupational underachievement, and poor adjustment to life stressors, including physical illness.

Children with DMDD have displayed elevated rates of social impairments, school suspension, and service use. Irritability in adolescence has predicted the development of major depressive and dysthymic disorders and generalized anxiety disorder (but not bipolar disorder) 20 yr later, as well as lower educational attainment and income.

ETIOLOGY AND RISK FACTORS

Current models of vulnerability to depressive disorders are grounded in gene by environment pathways. Genetic studies have repeatedly demonstrated the heritability of depressive disorders, with monozygotic twin studies finding concordance rates of 40-65%. In families, both bottom-up (children to parents) and top-down (parents to children) studies have shown a 2-4–fold bidirectional increase in depression among 1st-degree relatives. The exact nature of genetic expression remains unclear. Cerebral variations in structure and function (particularly serotonergic), the function of the hypothalamic–pituitary–adrenal axis, difficult temperament/personality (i.e., negative affectivity), and ruminative, self-devaluating cognitive style have been implicated as components of biologic vulnerability. The great majority of depressive disorders arise in youth with long-standing psychosocial difficulties, among the most predictive of which are physical/sexual abuse, neglect, chronic illness, school difficulties (bullying, academic failure), social isolation, family or marital disharmony, divorce/separation, parental psychopathology, and domestic violence. Longitudinal studies demonstrate the greater importance of environmental influences in children who become depressed compared to adults who become depressed. Factors shown to be protective against the development of depression include a positive relationship with a parent, better family function, closer parental supervision/monitoring/involvement, a prosocial peer group, higher IQ, and greater educational aspirations.

PREVENTION

Numerous experimental trials have sought to demonstrate the effectiveness of psychological or educational strategies in preventing the onset of depressive disorders in children and adolescents. These programs generally have provided information about the link between depressed mood and depressogenic thoughts and behaviors, and training in skills intended to modify these thoughts and behaviors. A meta-analytic review found small to moderate effects of these programs at both postintervention and follow-up (overall mean effect size: 0.16), with selective programs (targeted at high-risk groups) performing better than universal programs. A Cochrane review found some evidence that depression prevention programs may have a small favorable effect compared with no intervention, but no effect compared to attention controls.

SCREENING/CASE FINDING

Adolescents presenting in the primary care setting should be queried, along with their parent(s), about depressed mood as part of the routine clinical interview. A typical screening question would be "Everyone feels sad or angry some of the time, how about you (or your teen)?" The parents of younger children can be queried about overt signs of depression, such as tearfulness, irritability, boredom, or social isolation. A number of standardized broadband screening instruments widely used in the primary care setting (e.g., *Pediatric Symptom Checklist*, *Strengths and Difficulties Questionnaire*, *Vanderbilt ADHD Diagnostic Rating Scales*) have items specific to sad mood, and as such can be used to focus the interview.

The role of universal depression screening using standardized narrowband (depression-specific) instruments is unclear. A Cochrane review found that the use of depression screening in primary care has little or no impact on the recognition, management, or outcome of depression. The United States Preventive Services Task Force recommends the use of depression screening instruments only among adolescents, and only when systems are in place to ensure adequate follow-up. Targeted screening of known high-risk groups (e.g., youth who are homeless, refugees, attracted to the same sex, involved with child welfare or juvenile justice) or of youth experiencing known psychosocial adversities (see "Etiology/Risk Factors" above) or self-reporting a dysphoric mood may be a higher-yield case-finding strategy than universal screening (Fig. 26-1).

STEPPED MANAGEMENT

Because of the high rates of response to placebo and attention comparators as well as to brief therapy in the treatment of pediatric depression, clinical practice guidelines increasingly are advocating a stepped approach to the management of depressed youth. The stepped approach involves active case finding and initial management in the primary care setting if appropriate, with referral to increasingly intensive and specialized interventions as indicated by the clinical status of the patient.

EARLY INTERVENTION

Youth and/or their parents presenting in the primary care setting who self-report, or respond affirmatively to queries about, a distressing life experience or a depressed or irritable mood, should be offered the opportunity to talk about the situation with the pediatric practitioner (in private with the older youth as indicated). By engaging in active listening (e.g., "I hear how upset you have been feeling, tell me more about what happened to make you feel that way"), the pediatric practitioner can begin to assess the onset, duration, context, and severity of the symptoms, and associated dangerousness, distress, and functional impairment. In the absence of acute dangerousness (e.g., suicidality, psychosis, substance abuse) and significant distress or functional impairment, the pediatric practitioner can schedule a follow-up appointment within 1-2 wk to conduct a depression assessment. At this follow-up visit, to assist with decision making around appropriate level of care, a depression screening instrument can be administered (Table 26-4) and additional risk factors (see "Etiology/Risk Factors" above) can be explored.

For mild symptoms (manageable and not functionally impairing) and in the absence of major risk factors (e.g., suicidality, psychosis, substance use, history of depression, mania, or traumatic exposures, parental psychopathology [particularly depression]) or severe family dysfunction), guided self-help (anticipatory guidance) with watchful waiting may suffice. Guided self-help can include provision of educational materials (e.g., pamphlets, books, workbooks, internet sites) that provide information to the youth about dealing with stressful situations; and advice to parents about strengthening the parent-child relationship and modifying adverse environmental exposures (e.g., taking action against bullying, increasing opportunities for social interaction/support, protecting the child from exposure to marital discord) as depressogenic buffers. During the period of guided self-help, additional follow-up visits should be scheduled.

For youth who continue to have mild depression after a few weeks of guided self-help, supportive therapy by a mental health professional (ideally colocated in the primary care, school, or community setting) may be an appropriate subsequent step. Supportive psychotherapy, which can be delivered in individual or group formats, focuses on teaching thoughts (e.g., positive self-talk) and behaviors (e.g., pleasurable activities, relaxation, problem-solving, effective communication) known to ameliorate depressive symptoms, as well as providing concrete social or material problem-solving assistance to the youth or family as needed.

TREATMENT

For youth who have not responded to approximately 4-8 wk of supportive psychotherapy, or who from the outset exhibit moderate to severe, comorbid, or recurrent depression or suicidality, or who have a history of mania, traumatic exposures or severe family dysfunction or psychopathology, assessment and treatment in the specialty mental health setting by a child-trained mental health clinician should be provided (see Chapter 20). The mental health clinician should be

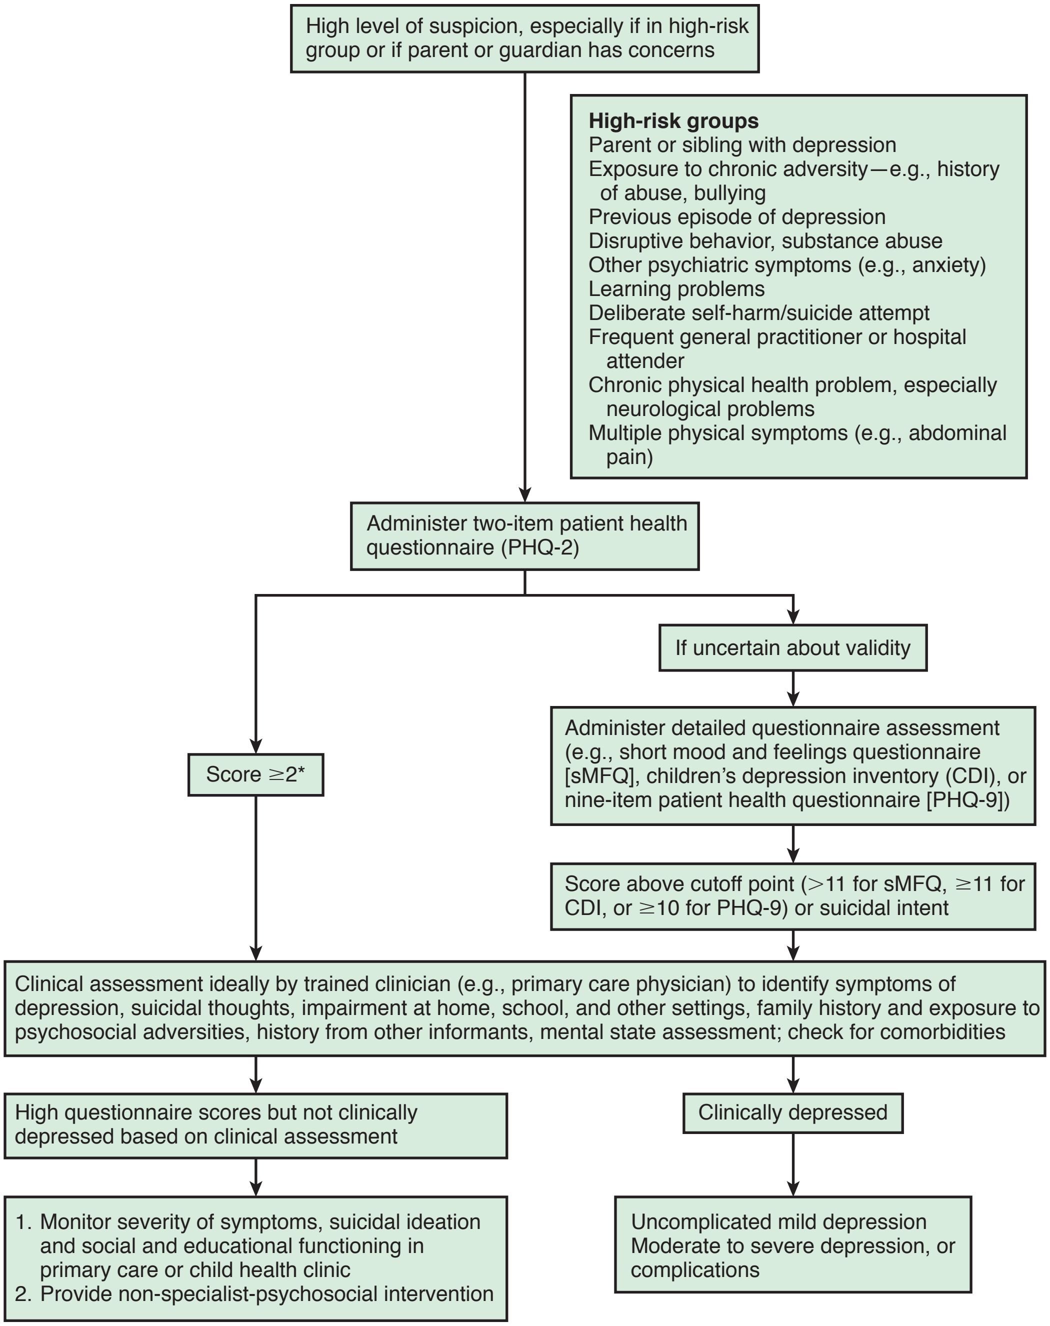

Figure 26-1 Detection of depression in adolescents in nonspecialist settings. *If patient scores < 2, generally no further action is needed. *(From Thapar A, Collishaw S, Pine DS, Thapar AK: Depression in adolescence.* Lancet *379:1056–1066, 2012. Fig. 1.)*

trained to the appropriate level of competence in the specific services he/she is asked to provide.

For moderate to severe depression, specific manualized psychotherapies, antidepressant medication, or a combination of the two should be provided. At present, there is insufficient evidence upon which to base definitive conclusions about the relative effectiveness of these treatments. The main goal of the acute treatment phase is to achieve response, which typically is defined as at least a 50% reduction in depressive symptoms as assessed by a standardized rating scale (see Table 26-4). Full recovery (i.e., absence of a depressive diagnosis) should be the ultimate treatment goal.

Clinical trials of acute treatments have generated support for the efficacy of ***cognitive-behavioral therapy*** **(CBT)** and ***interpersonal therapy*** as monotherapies in depressed youth, but effect sizes are modest (0.35 and 0.26, respectively). CBT focuses on identifying and correcting cognitive distortions that may lead to depressed mood and teaches problem-solving, behavior activation, social communication, and emotional regulation skills to combat depression. interpersonal therapy focuses on enhancing interpersonal problem solving and social communication to decrease interpersonal conflicts. Each of these therapies typically involves approximately 8-12 weekly visits.

Limited evidence suggests that family therapy may be more effective than no treatment on decreasing depression and improving family functioning. Because of the heterogeneity of the evidence base, however, the use of better supported therapies would at this time seem to be preferable over family therapy.

Two ***selective serotonin reuptake inhibitors*** **(SSRIs),** fluoxetine and escitalopram, are the only antidepressants approved by the FDA

Table 26-4 Depression-Specific Screening Instruments

NAME OF INSTRUMENT	INFORMANT(S)	AGE RANGE	NUMBER OF ITEMS
Preschool Feelings Checklist	Parent	3-5.6 yr	20

Reynolds Child Depression Scale	Youth	8-13 yr	30
Reynolds Adolescent Depression Scale-Second Edition	Youth	11-20 yr	30
Beck Depression Inventory	Youth	13+ yr	21
Patient Health Questionnaire-9	Youth	13-17 yr	9

for the treatment of depression, and fluoxetine alone is approved for preadolescents (see Chapter 21.1). These agents should be 1st-line for pharmacotherapy of pediatric depression, unless other factors (e.g., comorbidities, side-effect profiles, personal or family history of response to a specific medication) favor an alternative SSRI (preferably sertraline or citalopram). Resource limitations may necessitate provision of pharmacotherapy in the primary care setting; the safety and efficacy of this practice can be enhanced by regular consultation with a child and adolescent psychiatrist.

Randomized controlled trials **(RCTs)** of the effectiveness of antidepressants are mixed. Based on a large meta-analysis of RCTs, approximately 60% of youths with depression respond to antidepressants (vs. 50% for placebo), yielding a ***number needed to treat*** of 10, but only around 30% of medicated depressed youth experience symptom remission. Fluoxetine has consistently demonstrated greater efficacy, with a number needed to treat of 6, and is the only SSRI separating from placebo in studies of depressed preadolescents. Studies of other classes of antidepressant medications have not demonstrated clear superiority over placebo, and tricyclic medications and paroxetine in particular are not currently recommended for use in youth because of their clearly unfavorable risk : benefit profiles. The absolute risk for suicidal thoughts in youth with major depression approximates 3% (treated with antidepressant) versus 2% (given placebo), translating to a ***number needed to harm*** of 112.

Clinical severity, comorbidity, family conflict, low drug concentration, nonadherence, anhedonia, sleep difficulties, subsyndromal manic symptoms, and child maltreatment have all been related to treatment resistance. Approximately 50% of depressed youth failing to respond to the first SSRI respond after switching to a second antidepressant medication plus CBT, versus approximately 40% who respond to a second medication alone. For youth with psychotic depression, augmenting the antidepressant with an atypical antipsychotic medication should be considered, while monitoring closely for side effects.

The SSRIs have been well tolerated by children and adolescents. The most common side effects include irritability, gastrointestinal symptoms, sleep disturbance, restlessness, diaphoresis, headaches, changes in appetite, dizziness, dry mouth, and sexual dysfunction. Approximately 5% of youths, particularly children, develop increased impulsivity, agitation, and irritability (behavioral activation) on SSRIs, but the symptoms quickly resolve when the medication dose is reduced or the medication is discontinued. More rarely, the use of antidepressants has been associated with serotonin toxicity, increased predisposition to bleeding, abnormal heart rhythms (citalopram causes dose-dependent QT-interval prolongation and should not be prescribed at doses greater than 40 mg/day) and increased suicidal thoughts.

The initial dose of SSRI medication should be approximately one-half of the adult dose (e.g., 10 mg of fluoxetine). Some studies have reported that the half-lives of SSRIs other than fluoxetine are much shorter in children than in adults; therefore daily withdrawal side effects can be observed with these medications if they are administered once daily. Clinical response, tolerability, and emergence of behavioral activation, mania, or suicidal thoughts should be assessed frequently (preferably weekly) for the first 4 wk. If the youth has safely tolerated the antidepressant, the initial dose may be doubled at 4 wk if an adequate response (at least 50% reduction in symptom severity as measured by standardized rating scales) has not been achieved, with biweekly monitoring recommended. Patients who have responded by 8 wk can then be monitored less frequently (up to monthly) until remission (no longer meets diagnostic criteria) has been achieved. Patients treated in the primary care setting who have not responded by 8 wk or remitted by 12 wk should be referred to the specialty mental health setting for advanced care.

Because of the high rate of recurrence, successful treatment should continue for 6-12 mo. At the conclusion of treatment, all antidepressants should be discontinued gradually to avoid withdrawal symptoms (gastrointestinal upset, disequilibrium, sleep disruption, flu-like symptoms, sensory disturbances). Patients with recurrent (2 or more), chronic, or severe major depression can require treatment beyond 12 mo.

Table 26-5 summarizes screening, assessment, and treatment recommendations for depression.

LEVEL OF CARE

Most children and adolescents with mild to moderate depressive disorders can be safely and effectively treated as outpatients, provided that a clinically appropriate schedule of visits can be maintained through the phases of treatment. Inpatient treatment should be considered for youth who present with a high risk of suicide, serious self-harm, or self-neglect, or when the family is not able to provide an appropriate level of supervision or follow-up with outpatient treatment recommendations, or when comprehensive assessment for diagnostic clarity is needed. When considering inpatient admission for a young person with depression, the benefits of inpatient treatment needs to be balanced against potential detrimental effects, such as the loss of family and community support.

Table 26-5 Screening and Treatment for Major Depressive Disorder in Youths

RECOMMENDATION	ADOLESCENTS (12-18 Yr)	CHILDREN (7-11 Yr)
Screening	Screen (when systems for diagnosis, treatment, and follow-up are in place) Grade B	No recommendations Grade I (insufficient evidence)
Risk assessment	Risk factors for major depressive disorder include parental depression, having comorbid mental health or chronic medical conditions, and having experienced a major negative life event	
Screening tests	The following have been shown to do well in teens in primary care settings: Patient Health Questionnaire for Adolescents (PHQ-A) Beck Depression Inventory—Primary Care version (BDI-PC)	Screening instruments perform less well in younger children
Treatments	Among pharmacotherapies, fluoxetine, a SSRI, has been found efficacious. However, because of risk of suicidality, SSRIs should be considered only if clinical monitoring is possible. Various modes of psychotherapy, and pharmacotherapy combined with psychotherapy, have been found efficacious	Evidence on the balance of benefits and harms of treatment of younger children is insufficient for a recommendation

For a summary of the evidence systematically reviewed in making these recommendations, the full recommendation statement, and supporting documents, please go to http://www.AHRQ.gov/clinic/USPSTF/USPSCHDEPR.htm.

26.2 Bipolar and Related Disorders

Heather J. Walter, Natalija Bogdanovic, and David R. DeMaso

DESCRIPTION

The bipolar and related disorders include bipolar I, bipolar II, cyclothymic, and other specified/unspecified bipolar and related disorders, as well as bipolar and related disorder caused by another medical condition.

A manic episode (Table 26-6) is characterized by a distinct period of at least 1 wk in which there is an abnormally and persistently elevated, expansive, or irritable mood and abnormally and persistently increased goal-directed activity or energy that is present for most of the day, nearly every day (or any duration if hospitalization is necessary). The episode is associated with characteristic cognitive and behavioral symptoms, including disturbances in self-regard, speech, attention, thought, activity, impulsivity, and sleep. To diagnose ***bipolar I disorder***, criteria must be met for at least 1 manic episode, and the episode must not be better explained by a psychotic disorder. The manic episode may have been preceded by and may be followed by hypomanic or major depressive episodes. Bipolar I disorder is rated as mild, moderate, or severe in the same way as the depressive disorders (see Description section of Chapter 26.1).

To diagnose **bipolar II disorder,** criteria must be met for at least 1 hypomanic episode and at least 1 major depressive episode. A hypomanic episode is similar to a manic episode, but is briefer (at least 4 days) and less severe (causes less impairment in functioning, is not associated with psychosis, and would not require hospitalization). In bipolar II disorder, there must never have been a manic disorder, the episodes must not be better explained by a psychotic disorder, and the symptoms of depression or the unpredictability caused by frequent alternation between periods of depression and hypomania must cause clinically significant distress or functional impairment. Bipolar II disorder is rated as mild, moderate, or severe in the same way as bipolar I disorder.

Cyclothymic disorder is characterized by a period of at least 1 yr (in children and adolescents) in which there are numerous periods with hypomanic and depressive symptoms that do not meet criteria for a hypomanic episode or a major depressive episode, respectively.

Other specified/unspecified bipolar and related disorders (subsyndromal bipolar disorder) applies to presentations in which symptoms characteristic of a bipolar and related disorder are present and cause distress or functional impairment, but do not meet the full criteria for any of the disorders in this diagnostic class. Although this diagnosis (formerly known as bipolar disorder, not otherwise specified)

Table 26-6 DSM-5 Diagnostic Criteria for a Manic Episode

A. A distinct period of abnormally and persistently elevated, expansive, or irritable mood and abnormally and persistently increased goal-directed activity or energy, lasting at least 1 wk and present most of the day, nearly every day (or any duration if hospitalization is necessary).
B. During the period of mood disturbance and increased energy or activity, 3 (or more) of the following symptoms (4 if the mood is only irritable) are present to a significant degree and represent a noticeable change from usual behavior:
 1. Inflated self-esteem or grandiosity.
 2. Decreased need for sleep (e.g., feels rested after only 3 hr of sleep).
 3. More talkative than usual or pressure to keep talking.
 4. Flight of ideas or subjective experience that thoughts are racing.
 5. Distractibility (i.e., attention too easily drawn to unimportant or irrelevant external stimuli), as reported or observed.
 6. Increase in goal-directed activity (either socially, at work or school, or sexually) or psychomotor agitation (i.e., purposeless non-goal-directed activity).
 7. Excessive involvement in activities that have a high potential for painful consequences (e.g., engaging in unrestrained buying sprees, sexual indiscretions, or foolish business investments).
C. The mood disturbance is sufficiently severe to cause marked impairment in social or occupational functioning or to necessitate hospitalization to prevent harm to self or others, or there are psychotic features.
D. The episode is not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication, other treatment) or to another medical condition.

Note: A full manic episode that emerges during antidepressant treatment (e.g., medication, electroconvulsive therapy) but persists at a fully syndromal level beyond the physiologic effect of that treatment is sufficient evidence for a manic episode and, therefore, a bipolar I diagnosis.

Note: Criteria A-D constitute a manic episode. At least 1 lifetime manic episode is required for the diagnosis of bipolar I disorder.

From the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, p. 124.

heretofore had frequently been applied to children with severe and chronic mood and behavioral dysregulation who did not precisely fit other diagnostic categories, the empiric support for the validity of this practice has been sparse. Many children who formerly received this diagnosis will meet criteria for DMDD (see Chapter 26.1).

In adolescents, the clinical manifestations of bipolar disorder are similar to those in adults, and psychosis (delusions, hallucinations) often is an associated symptom. Mood in a manic episode is often described as euphoric, excessively cheerful, high, or "feeling on top of the world." During the episode, the adolescent may engage in multiple new projects that are initiated with little knowledge of the topic and often at unusual hours (in the middle of the night). Inflated self-esteem is usually present, ranging from uncritical self-confidence to marked grandiosity, and may reach delusional proportions. The adolescent may sleep little if at all for days at a time and nonetheless feel rested and full of energy. Speech can be rapid, pressured, and loud and characterized by jokes, puns, amusing irrelevancies, and theatricality. Frequently there is a flight of ideas evidenced by a nearly continuous flow of accelerated speech, with abrupt shifts from one topic to another. Distractibility is evidenced by an inability to censor irrelevant extraneous stimuli, which often prevents an individual with mania from engaging in a rational conversation. The expansive mood, grandiosity, and poor judgment often lead to reckless involvement in activities with high potential for personal harm.

There is controversy about the applicability of the bipolar diagnostic criteria to prepubertal children. It may be developmentally normal for children to be elated, expansive, grandiose, or talkative, reducing the specificity of these symptoms to this disorder. In addition, the distractibility, overactivity, and impulsivity formerly ascribed to bipolar disorder by some investigators may be better explained by a diagnosis of ADHD. The presentations of severe irritability formerly diagnosed as bipolar disorder may be better captured by the diagnosis of DMDD.

EPIDEMIOLOGY

The lifetime prevalence of the bipolar disorders among adults approximates 1-3%; rates among youth generally have been less than 1%. For bipolar I, the male : female ratio approximates 1.1 : 1.

CLINICAL COURSE

The mean age of onset of the first manic episode is approximately 18 yr for bipolar I disorder. Premorbid problems are common in bipolar disorder, especially difficulties with mood and behavioral regulation. Premorbid anxiety also is common. The early course of adolescent-onset bipolar disorder appears to be more chronic and refractory to treatment than adult-onset bipolar disorder. Comorbidity predicts functional impairment and age at onset predicts duration of episodes. Sleep impairment and family conflict are inversely related to favorable treatment response, suggesting important targets for treatment. The bipolar disorders are highly recurrent, and more than 80% of bipolar I patients go on to have additional mood episodes. Recurrent episodes can approximate 4 in 10 yr, with the interepisode interval shortening as the patient ages. Although the majority of patients with bipolar I return to a fully functional level between episodes, approximately one-third continue to be symptomatic and functionally impaired between episodes. In a 14 yr follow-up study, children 4-16 yr of age exceeding the clinical cutpoint for the dysregulation ("bipolar") profile on the Child Behavior Checklist were found to have increased rates of anxiety, mood, disruptive behavior, and substance abuse disorders in adulthood.

DIFFERENTIAL DIAGNOSIS

A number of psychiatric disorders, general medical conditions, and medications can generate manic-like symptoms and must be distinguished from the bipolar and related disorders. The psychiatric disorders include ADHD, oppositional defiant, intermittent explosive, posttraumatic stress, depressive, anxiety, substance abuse, and borderline personality disorders. Medical conditions include neurologic disorders, endocrine disorders, infectious diseases, tumors, anemia, uremia, and vitamin deficiencies. Medications include androgens, bronchodilators, cardiovascular medications, corticosteroids, chemotherapy agents, thyroid preparations, and certain psychiatric medications (benzodiazepines, antidepressants, stimulants). The diagnosis of a bipolar disorder should be made after these other explanations for the observed symptoms have been ruled out.

COMORBIDITY

Nearly 75% of individuals with bipolar disorders have co-occurring anxiety disorders, and nearly 50% have co-occurring attention, disruptive/impulse control/conduct, and substance use disorders.

SEQUELAE

The lifetime risk of suicide in individuals with bipolar disorder is estimated to be at least 15 times that of the general population. Youths with bipolar disorders are also at high risk for substance abuse, antisocial behavior, impaired academic performance, impaired family and peer relationships, and poor adjustment to life stressors.

ETIOLOGY/RISK FACTORS

Twin studies suggest the heritability of bipolar disorder is greater than 60%. Offspring of parents with bipolar disorders are at high risk for early-onset bipolar disorders, and there is an average 10-fold increased risk among adult relatives of individuals with bipolar disorder, with the magnitude of risk increasing with the degree of kinship. Bipolar disorder and schizophrenia likely share a genetic origin, reflected in familial co-aggregation of the two disorders.

Dysthymic (sad), cyclothymic (labile), or hyperthymic (irritable) temperaments may presage eventual bipolar disorder. Premorbid anxiety and dysphoria also are common, and approximately 20% of youth with major depression go on to experience manic episodes by adulthood. Similar to findings in adults, factors that predict the eventual development of mania in depressed youth include a depressive episode characterized by rapid onset, psychomotor retardation, and psychotic features, a family history of affective disorders, especially bipolar disorder, and a history of mania or hypomania after treatment with antidepressants.

PREVENTION

Although empiric support is sparse, 1 randomized controlled study demonstrated the effectiveness of family-focused treatment versus an educational control in hastening and sustaining recovery from mood symptoms in a high familial risk cohort of youth with subsyndromal symptoms of mania. Family-focused treatment is a manualized psychoeducational intervention designed to reduce family stress, conflict, and affective arousal by enhancing communication and problem-solving between youth and their caregivers. Pharmacologic interventions for subsyndromal mania have produced equivocal results.

CASE FINDING

Cardinal manic symptoms of elation and grandiosity occurring in adolescents as a discrete episode should alert pediatric practitioners to the possibility of a bipolar or related disorder. Because of the complexity of these disorders, any suspected cases should be referred to the specialty mental health setting for comprehensive assessment (see Chapter 20) and treatment (see Chapter 21).

TREATMENT

For mania in bipolar I disorder, medication is the primary treatment. Among traditional mood stabilizer medications (lithium carbonate, divalproex sodium, carbamazepine), only lithium is approved by the FDA for the treatment of bipolar disorder from age 12 yr (see Chapter 21.1). At present lithium has only open-label empirical support, with an overall response rate approximating 40%. There is no RCT evidence supporting the efficacy of divalproex sodium or carbamazepine. No other anticonvulsant medications sometimes used for the treatment of mania (oxcarbazepine, lamotrigine, topiramate) have FDA approval or RCT evidence of efficacy. In contrast, atypical antipsychotic medications (e.g., quetiapine, aripiprazole, ziprasidone, risperidone, olanzapine) have an overall 66% response with significant separation from placebo/active comparator in RCTs, and as such are considered to be

1st-line treatments for mania. The FDA has approved aripiprazole, risperidone, and quetiapine for the treatment of bipolar disorder from age 10 yr, and olanzapine from age 13 yr (see Chapter 21.1). The choice of antipsychotic medication is based upon factors such as side-effect profiles, adherence considerations, and a positive response of a family member.

Medication trials should be systematic, and the duration of trials should be sufficient (generally 6-8 wk) to determine the agent's effectiveness. Care should be taken to avoid unnecessary polypharmacy, in part by discontinuing agents that have not demonstrated significant benefit. Because all of these medications are associated with significant side effects, careful monitoring of baseline and follow-up indices is imperative. Side effects of lithium include reduced urine concentrating ability, hypothyroidism, hyperparathyroidism, weight gain, and renal failure. Acute overdose (level > 1.5 mEq/L) manifests with neurologic symptoms (tremor, ataxia, nystagmus, hyperreflexia, myoclonus, slurred speech, delirium, coma, seizures), and altered renal function. Toxicity is enhanced when dehydrated or with drugs that affect renal function (nonsteroidal antiinflammatory drugs, angiotensin-converting enzyme inhibition) Neuroleptic malignant syndrome has been reported in patients also taking antipsychotic drugs. Atypical antipsychotics cause weight gain, metabolic aberrations (diabetes, hyperlipidemia), and cardiac effects. Withdrawal of medication has been associated with increased risk of relapse.

The regimen needed to stabilize acute mania should be maintained for 12-24 mo. Maintenance therapy is often needed for adolescents with bipolar I disorder, and some patients need lifelong medication. Any attempts to discontinue prophylactic medication should be done gradually, while closely monitoring the patient for relapse.

For depression in bipolar II disorder, antidepressant medication may be used once a mood-stabilizing medication has been initiated. Lamotrigine as adjunctive or monotherapy also may be helpful for adolescents with bipolar depression. Comorbid ADHD can be treated with stimulant medication once a mood-stabilizing medication has been initiated.

Psychotherapy is a potentially important adjunctive treatment for the bipolar disorders. However, a Cochrane review of 7 RCTs of family interventions found only heterogeneous evidence of effectiveness, precluding definitive conclusions about their use. Factors known to adversely influence response to therapy include high-conflict families and sleep impairment, suggesting the importance of targeting these factors in treatment.

LEVEL OF CARE

Most youths with bipolar disorders can be safely and effectively treated as outpatients, provided that an appropriate schedule of visits and laboratory monitoring can be maintained through the course of treatment. Youths who are suicidal or psychotic typically require inpatient care.

Chapter 27
Suicide and Attempted Suicide

David R. DeMaso, Heather J. Walter, and Elizabeth A. Wharff

Youth suicide is a major and tragic public health problem. For youth between the ages of 15 and 24 yr in the United States, suicide is the 3rd leading cause of death, with approximately 4,600 lives lost each year. Globally, suicide rates for youth ages 15-19 yr are 7.4/100,000 persons, the 4th leading cause of death for males and the 3rd for females. There are a number of psychiatric, social, cultural, and environmental risk factors for suicidal behavior, and knowledge of these risk factors can facilitate identification of youths at highest risk (Fig. 27-1).

EPIDEMIOLOGY

Suicidal Ideation and Attempts

Based on the 2011 Youth Risk Behavior Survey, almost one-third of 9th through 12th grade students nationwide in the United States felt so sad or hopeless almost every day for 2 or more wk in a row during the previous year that they stopped doing some usual activities. During that same time period, nearly 16% of the students reported that they had seriously considered attempting suicide and 8% reported that they had actually attempted suicide. A suicide attempt in the previous year that resulted in an injury, poisoning, or overdose that had to be treated by a doctor or nurse was reported by more than 2% of students.

It is estimated that for every completed youth suicide, as many as 200 suicide attempts are made. Ingestion of medication is the most common method of attempted suicide. The 15-19 yr old age group is the most likely to intentionally harm themselves by ingestion, receive treatment in emergency departments, and survive. Attempts are more common in adolescent females than males (approximately 4 : 1), and in Hispanic females compared to their non-Hispanic counterparts. Gay, lesbian, bisexual, and transgender youths also have disproportionately high rates of suicide attempts. Attempters who have made prior suicide attempts, who used a method other than ingestion, and who still want to die are at increased risk for completed suicide.

Suicide Completions

In the United States, completed suicide is very rare before puberty. Rates of completed suicide increase steadily across adolescence into young adulthood, peaking in the early 20s. In the past 60 yr, the suicide rate has quadrupled among 15-24 year old males and has doubled for females of the same age. The male : female ratio for completed suicide rises with age from 3 : 1 in children to approximately 4 : 1 in 15-24 yr olds, and to greater than 6 : 1 among 20-24 yr olds.

Native Americans/Alaska Natives have highest rates of completed suicide of all ethnic groups, with nearly 21 deaths per 100,000. White youth are the next highest at almost 12 deaths per 100,000. The ethnic groups with the lowest risk are African-Americans, Hispanics, Asians, and Pacific Islanders. Over time the suicide rate among African-American, Hispanic, and other minority males has increased, while the rate among white males has remained steady.

Access to means has been linked to suicide rates among different groups in the population and different geographical areas of the world (Fig. 27-2). Firearms are the most common method used to complete suicide in the United States, and account for 56% of male suicides and 30% of female suicides. In females, poisonous ingestions, especially overdoses of medications, are the most common method used to complete suicide, and account for 37% of female suicides, compared to only 12% of male suicides. Hanging is the third most common method used to complete suicide and accounts for 25% of male and female suicides. Firearms are the most lethal method of suicide completion; the death rate with respect to firearms is approximately 80-90%, whereas the death rate is only 1.5-4% for overdoses.

RISK FACTORS

In addition to age, race/ethnicity, and a history of a previous suicide attempt, there are multiple risk factors that predispose youths to suicide (Table 27-1).

Preexisting Mental Disorder

Approximately 90% of youths who complete suicide have a preexisting psychiatric illness, most commonly major depression (see Chapter 26.1). Among females, chronic anxiety, especially panic disorder, also is associated with suicide attempts and completion (see Chapter 25).

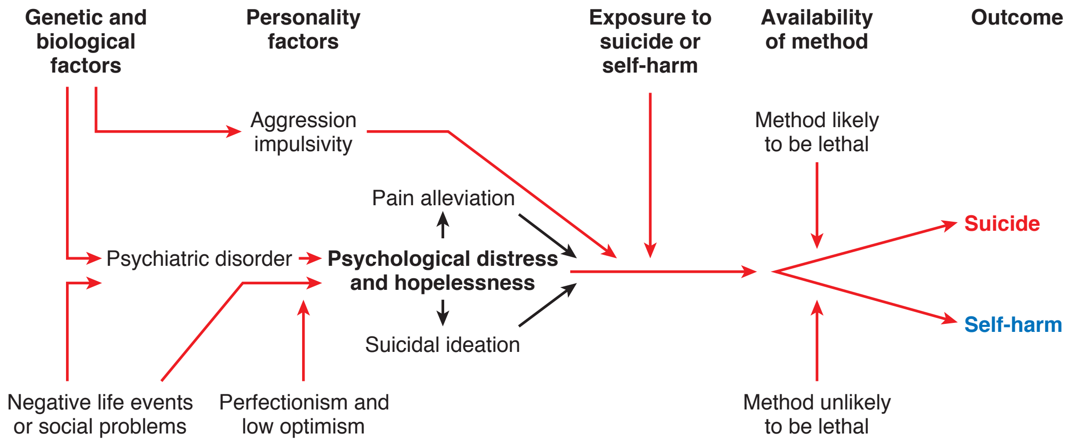

Figure 27-1 Key risk factors for adolescent self-harm and suicide. *(From Hawton K, Saunders KEA, O'Connor RC: Self-harm and suicide in adolescents.* Lancet *379:2373–2380, 2012, Fig. 2.)*

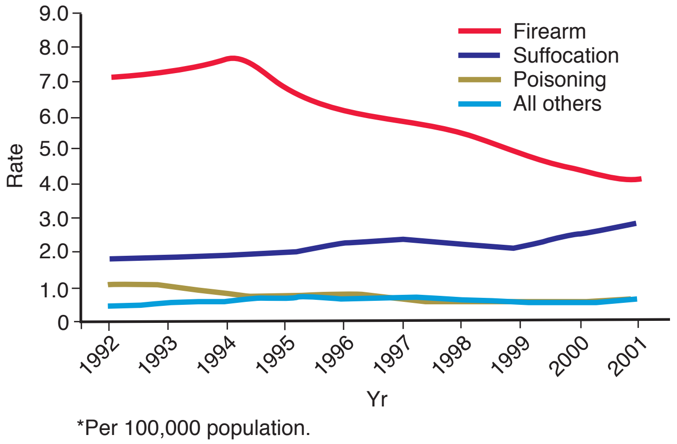

Figure 27-2 Annual suicide rates among persons age 15-19 yr, by year and method, United States, 1992-2001. *(From Centers for Disease Control and Prevention: Methods of suicide among persons aged 10-19 years, United States, 1992-2001.* MMWR Morb Mortal Wkly Rep *53:471-474, 2004.)*

Among males, conduct disorder and substance use convey increased risk. Comorbidity of a substance use disorder (see Chapter 114), a depressive disorder (see Chapter 26.1), and conduct disorder (see Chapter 29.1) are linked to suicide by firearm. Schizophrenia spectrum disorders (see Chapter 31) are linked to suicide attempts and completions.

Cognitive Distortions

Negative self-attributions can contribute to the hopelessness that is commonly associated with suicidality; hopelessness may contribute to approximately 55% of the explained variance in continued suicidal ideation. Many youth who are suicidal hold negative views of their own competence, have poor self-esteem, and have difficulty identifying sources of support or reasons to live. Many youngsters lack the coping strategies necessary to manage strong emotions and instead tend to catastrophize and engage in all-or-nothing thinking.

Biologic Factors

Postmortem studies show that there are observable differences between the brains of individuals who have completed suicide and those who died from other causes. The brain systems that may be related to suicide completion are the serotonergic system, adrenergic system, and the hypothalamic–pituitary axis. Family history of mental disorders also is linked to completed suicide.

Table 27-1	Risk Factors for Self-Harm and Suicide in Adolescents
SOCIODEMOGRAPHIC AND EDUCATIONAL FACTORS	
Sex (female for self-harm and male for suicide)—most countries*	
Low socioeconomic status*	
Lesbian, gay, bisexual, or transgender sexual orientation	
Restricted educational achievement*	
INDIVIDUAL NEGATIVE LIFE EVENTS AND FAMILY ADVERSITY	
Parental separation or divorce*	
Parental death*	
Adverse childhood experiences*	
History of physical or sexual abuse	
Parental mental disorder*	
Family history of suicidal behavior*	
Marital or family discord	
Bullying	
Interpersonal difficulties*	
PSYCHIATRIC AND PSYCHOLOGICAL FACTORS	
Mental disorder,* especially depression, anxiety, attention deficit hyperactivity disorder	
Drug and alcohol misuse*	
Impulsivity	
Low self-esteem	
Poor social problem-solving	
Perfectionism	
Hopelessness*	

All the factors in the panel have been shown to be related to self-harm.
*Shown to be related to suicide.
From Hawton K, Saunders KEA, O'Connor: Self-harm and suicide in adolescents. Lancet *379:2373–2380, 2012, Panel 1, p. 2375.*

Social, Environmental, and Cultural Factors

Of youths who attempt suicide, 65% can name a precipitating event for their action. Most adolescent suicide attempts are precipitated by stressful life events (e.g., academic or social problems, being bullied, trouble with the law, family instability, questioning one's sexual orientation, a newly diagnosed medical condition, or a recent or anticipated loss).

Suicide attempts may also be precipitated by exposure to news of another person's suicide or by reading about or viewing a suicide portrayed in a romantic light in the media. Media coverage of suicide is linked to fluctuating incidence rates of suicides, particularly among adolescents. Glorification or sensationalization of suicide in the media has found to be associated with an increase in suicides. When media coverage includes a detailed description of specific means used, the use of that particular method may increase in the overall population.

For some immigrants, suicidal ideation can be associated with high levels of acculturative stress, especially in the context of family separation and limited access to supportive resources. Physical and sexual abuse can also increase one's risk of suicide with 15-20% of female suicide attempters having had a history of abuse. There is a general association between family conflict and suicide attempts; this association is strongest in children and early adolescents. Family psychopathology and a family history of suicidal behavior convey excess risk. The lack of supportive social relations with peers, parents, and school personnel have an interactive relationship in increasing the risk of suicide among youth.

Protective Factors

Protective factors can provide a counterbalance for those contemplating suicide. They may include a sense of family responsibility, life satisfaction, social support, coping and problem-solving skills, religious faith, intact reality testing, and solid therapeutic relationships (e.g., pediatrician, teacher, therapist).

ASSESSMENT AND INTERVENTION

Pediatric practitioners should consider suicide potential and the need for mental health assessment in the context of adverse information elicited in child/parent psychosocial histories (e.g., HEADSS Psychosocial Risk Assessment; see Table 20-2 in Chapter 20), screening measure scores out of the normal range (e.g., Pediatric Symptom Checklist), or self-reported statements or behaviors from patients and/or parents.

All suicidal ideation and attempts should be taken seriously and require a thorough assessment by a child-trained mental health clinician to evaluate the youth's current state of mind, underlying psychiatric conditions, and ongoing risk of harm. Emergency mental health assessment is needed for immediate threat to self (i.e., suicidal intent and plan); urgent mental health assessment (48-72 hr) is needed for severe psychiatric symptoms, significant change in overall functioning, and/or suicidal ideation without intent or plan. Routine mental health assessment is appropriate for mild to moderate psychiatric symptoms without suicidal ideation.

Pediatric practitioners should expect the mental health clinician to evaluate the presence and degree of suicidality and underlying risk factors. The reliability and validity of child interviewing is affected by the child's level of cognitive development and well as their understanding of the relationship between their emotions and behavior. Confirmation of the youth's suicidal behavior can be obtained from information gathered by interviewing others who know the child or adolescent. It is not unusual for there to be a discrepancy between patient and parent reports, with both children and adolescents being more likely to disclose suicidal ideation and suicidal actions than their parents.

In the mental health assessment, suicidal ideation can be assessed by explicit questions posed in a nonjudgmental, noncondescending, matter-of-fact approach. The *Ask Suicide-Screening Questionnaire* is a validated 4-item measure that has been shown in the emergency room setting to have high sensitivity and negative predictive value in identifying youth at risk for suicide ideation and behavior: *(1) In the past few weeks, have you felt that you or your family would be better off if you were dead? (2) In the past few weeks, have you wished you were dead? (3) In the past weeks, have you been having thoughts about killing yourself? (4) Have you ever tried to kill yourself?*

The assessment of a suicidal attempt should include a detailed exploration of the hours immediately preceding the attempt to identify precipitants as well as the circumstances of the attempt itself so as to fully understand the patient's intent and potential lethality. The calculation of the level of suicide concern is complex requiring a determination across a spectrum of risk (Fig. 27-3). At the low end of the risk spectrum are youth with thoughts of death or wanting to die, but without suicidal thoughts, intent, or a plan. Those with highly specific suicide plans, preparatory acts or suicide rehearsals, and clearly articulated intent are at the high end. A suicidal history, presently impaired judgment (as seen in altered mental states including depression, mania, anxiety, intoxication, substance abuse, psychosis, trauma-reactive, hopelessness, rage, humiliation, impulsivity) as well as poor social support further exacerbates the heightened risk. Among adolescents who consider self-harm, those who carry out (enactors) self-injury are more likely to have family or friends (or think that their peers) engaged in self harm, and are more impulsive than those who only have thoughts of self-harm (ideators).

For youth who are an imminent danger to themselves, inpatient level of psychiatric care is necessary to ensure safety, clarify diagnoses, and comprehensively plan treatment. These patients can be hospitalized voluntarily or involuntarily. It is helpful for the pediatric practitioner to have an office protocol to follow in these situations. This protocol should take into consideration state laws regarding involuntary hospitalization, transportation options, nearest emergency assessment site, necessary forms for hospitalization, and available emergency mental health consultants.

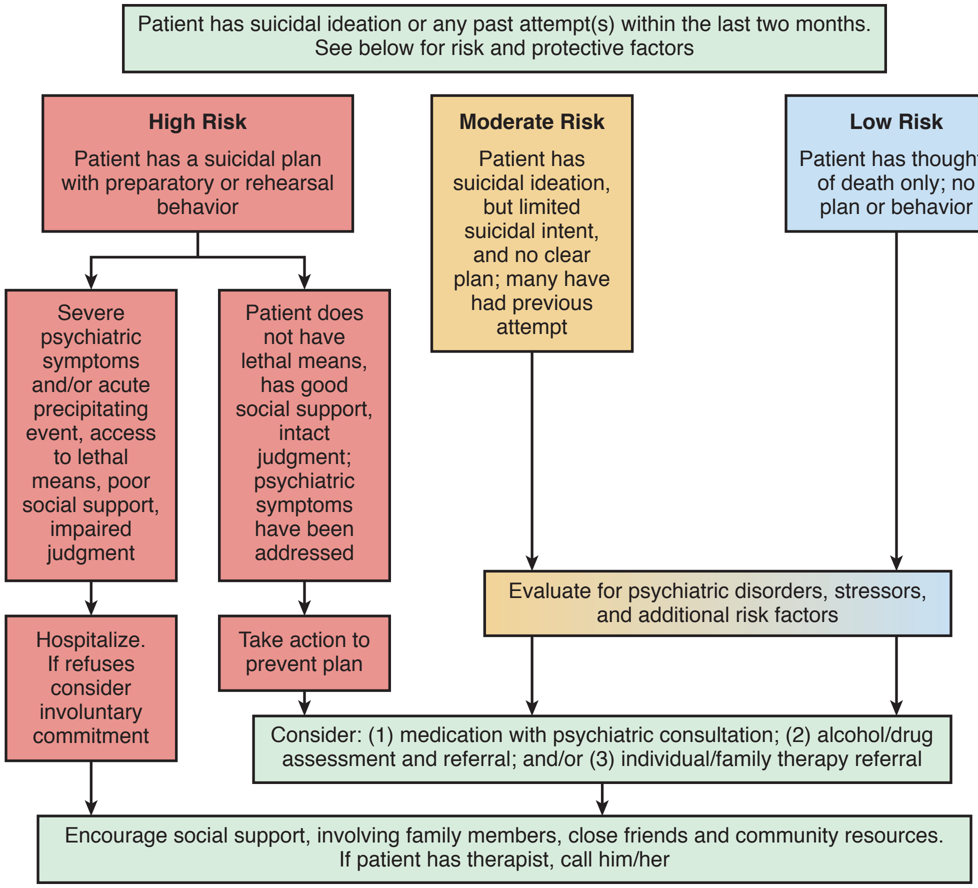
For those youth suitable for treatment in the outpatient setting, an appointment should be scheduled within a few days with a mental health clinician. Ideally, this appointment should be scheduled before leaving the assessment venue, as nearly 50% of those who attempt suicide fail to follow through with the mental health referral. A procedure should be in place to contact the family if the family fails to complete the referral.

Through follow-up office visits, pediatric practitioners can help support and facilitate the implementation of psychotherapies (e.g., cognitive-behavioral therapy, dialectical behavioral therapy, interpersonal therapy, and/or family therapy) that target the specific psychiatric disorders and the emotional dysphoria or behavioral dysregulation that accompany suicidal ideation or behavior. In conjunction with a child and adolescent child psychiatrist, psychotropic medications may be used as indicated to treat underlying psychiatric disorders. Pediatric practitioners also can encourage social connectedness to peers and to community organizations (e.g., school or church), as well as promote help-seeking (e.g., talking to a trusted adult when distressed) and wellness (e.g., sleep, exercise, relaxation, nutrition) behaviors. In the unfortunate circumstance of a completed suicide, pediatricians can offer support to the family, particularly by monitoring for adverse bereavement responses in siblings and parents.

PREVENTION

Suicide prevention is of high global importance. Yet, even in high-risk populations suicide is a comparatively rare event. Even the aforementioned risk factors associated with suicide are relatively common and individually not strong predictors of suicide. The assessment is complicated by patients that may attempt to conceal their suicide thoughts and by those who express suicidal thoughts without serious intent. Suicide screening has been challenging because most screening instruments have variable sensitivity and specificity. In addition, the burden of follow-up mental health evaluations for those who screen positive has been daunting. Although primary care–feasible screening tools may be help to identify some adults at increased risk for suicide, they have, to date, demonstrated limited ability to detect suicide risk in adolescents.

Prevention strategies in the pediatric medical home include training staff to recognize and respond to the warning signs of suicide, screening for and treating depression, educating patients/parents about warning signs for suicide, and restricting access to modes of lethal self-harm. Youth have increased rates of suicide attempts and completions if they live in homes where firearms are present and available. When recommended by their primary care providers, most parents restrict access of their children to guns and medications. Pediatric practitioners should consider counseling parents to either remove firearms from the home entirely or securely lock guns and ammunition in separate locations. Anecdotal evidence suggests youth frequently know where guns and keys to gun cabinets are kept, even though parents may think they do not. The same recommendation applies to restricting access to potentially lethal prescription and nonprescription



Risk Factors
- **Suicidal behavior:** history of prior suicide attempts, aborted suicide attempts, or self-injurious behavior.
- **Family history:** of suicide, attempts, or psychiatric diagnoses, especially those requiring hospitalization.
- **Current/past psychiatric disorders:** especially mood disorders (e.g., depression, bipolar disorder), psychotic disorders, alcohol/substance abuse, TBI, PTSD, personality disorders (e.g., borderline PD). ***Co-morbidity*** *with other psychiatric and/or substance abuse disorders and recent onset of illness increase risk.*
- **Key symptoms:** anhedonia, impulsivity, hopelessness, anxiety/panic, insomnia, command hallucinations, intoxication, oppositionality, and conduct problems.
- **Precipitants/stressors:** triggering events leading to humiliation, shame or despair (i.e., loss of relationship, financial, or health status – real or anticipated).
- **Chronic medical illness** (esp. CNS disorders, pain)
- **History of current abuse or neglect.**

Protective Factors
Protective factors, even if present, may not counteract significant acute risk.
- **Internal:** ability to cope with stress, religious beliefs, frustration tolerance.
- **External:** responsibility to family, positive therapeutic relationships, social supports

medications (e.g., containers of more than 25 acetaminophen tablets) and alcohol. *These approaches emphasize the importance of restriction of access to means for suicide to prevent self-harm.*

Screening for suicide in schools is also fraught with problems related to low specificity of the screening instrument and paucity of referral sites, as well as poor acceptability among school administrators. Gatekeeper (e.g., student support personnel) training appears effective in improving skills among school personnel and is highly acceptable to administrators but has not been shown to prevent suicide. School curricula (e.g., *Signs of Suicide*) have shown some preventive potential by teaching students to recognize the signs of depression and suicide in themselves and others, and to provide students with specific action steps necessary for responding to these signs. Peer helpers have not generally been shown to be efficacious.

Chapter 28

Eating Disorders

Richard E. Kreipe

Eating disorders (EDs) are characterized by body dissatisfaction related to overvaluation of a thin body ideal associated with dysfunctional patterns of cognition and weight-control behaviors that result in significant biologic, psychological, and social complications. Although largely affecting white, adolescent girls, EDs also affect boys and cross all racial, ethnic, and cultural boundaries. Early intervention in EDs improves outcome.

Table 28-1 DSM-5 Diagnostic Criteria for Anorexia Nervosa

A. Restriction of energy intake relative to requirements, leading to a significantly low body weight in the context of age, sex, developmental trajectory, and physical health. Significantly low weight is defined as a weight that is less than minimally normal or, for children and adolescents, less than that minimally expected.
B. Intense fear of gaining weight or of becoming fat, or persistent behavior that interferes with weight gain, even though at a significantly low weight.
C. Disturbance in the way in which one's body weight or shape is experienced, undue influence of body weight or shape on self-evaluation, or persistent lack of recognition of the seriousness of the current low body weight.

Specify whether:

Restricting type (ICD-10-CM code F50.01): During the last 3 mo, the individual has not engaged in recurrent episodes of binge eating or purging behavior (i.e., self-induced vomiting or the misuse of laxatives, diuretics, or enemas). This subtype describes presentations in which weight loss is accomplished primarily through dieting, fasting, and/or excessive exercise.

Binge-eating/purging type (ICD-10-CM code F50.02): During the last 3 mo, the individual has engaged in recurrent episodes of binge eating or purging behavior (i.e., self-induced vomiting or the misuse of laxatives, diuretics, or enemas).

Specify if:

In partial remission: After full criteria for anorexia nervosa were previously met, Criterion A (low body weight) has not been met for a sustained period, but either Criterion B (intense fear of gaining weight or becoming fat or behavior that interferes with weight gain) or Criterion C (disturbances in self-perception of weight and shape) is still met.

In full remission: After full criteria for anorexia nervosa were previously met, none of the criteria have been met for a sustained period of time.

Specify current severity:

The minimum level of severity is based, for adults, on current body mass index (BMI) (see below) or, for children and adolescents, on BMI percentile. **The ranges below are derived from World Health Organization categories for thinness in adults; for children and adolescents, corresponding BMI percentiles should be used.** The level of severity may be increased to reflect clinical symptoms, the degree of functional disability, and the need for supervision.

Mild: BMI ≥ 17 kg/m^2
Moderate: BMI 16–16.99 kg/m^2
Severe: BMI 15–15.99 kg/m^2
Extreme: BMI < 15 kg/m^2

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, p. 338–339.

Table 28-2 DSM-5 Diagnostic Criteria for Bulimia Nervosa

A. Recurrent episodes of binge eating. An episode of binge eating is characterized by both of the following:
   1. Eating, in a discrete period of time (e.g., within any 2 hr period), an amount of food that is definitely larger than what most individuals would eat in a similar period of time under similar circumstances.
   2. A sense of lack of control over eating during the episode (e.g., a feeling that one cannot stop eating or control what or how much one is eating).
B. Recurrent inappropriate compensatory behaviors in order to prevent weight gain, such as self-induced vomiting; misuse of laxatives, diuretics, or other medications; fasting; or excessive exercise.
C. The binge eating and inappropriate compensatory behaviors both occur, on average, at least once a week for 3 mo.
D. Self-evaluation is unduly influenced by body shape and weight.
E. The disturbance does not occur exclusively during episodes of anorexia nervosa.

Specify if:

In partial remission: After full criteria for bulimia nervosa were previously met, some, but not all, of the criteria have been met for a sustained period of time.

In full remission: After full criteria for bulimia nervosa were previously met, none of the criteria have been met for a sustained period of time.

Specify current severity:

The minimum level of severity is based on the frequency of inappropriate compensatory behaviors (see below). The level of severity may be increased to reflect other symptoms and the degree of functional disability.

Mild: An average of 1-3 episodes of inappropriate compensatory behaviors per week.
Moderate: An average of 4-7 episodes of inappropriate compensatory behaviors per week.
Severe: An average of 8-13 episodes of inappropriate compensatory behaviors per week.
Extreme: An average of 14 or more episodes of inappropriate compensatory behaviors per week.

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, p. 345.

DEFINITIONS

Anorexia nervosa (AN) involves significant overestimation of body size and shape, with a relentless pursuit of thinness that typically combines excessive dieting and compulsive exercising in the **restrictive** subtype; in the **binge-purge** subtype, patients might intermittently overeat and then attempt to rid themselves of calories by vomiting or taking laxatives, still with a strong drive for thinness (Table 28-1). **Bulimia nervosa (BN)** is characterized by episodes of eating large amounts of food in a brief period, followed by compensatory vomiting, laxative use, and exercise or fasting to rid the body of the effects of overeating in an effort to avoid obesity (Table 28-2).

Children and adolescents with EDs may not fulfill criteria for AN or BN in the new *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) but fall into a new subcategory of **Atypical AN,** or a new category of **Avoidant Restrictive Food Intake Disorder (ARFID)** (Table 28-3), that includes a group of conditions in which food intake is restricted or avoided due to adverse feeding or eating experiences or the sensory qualities of food, resulting in significant nutritional deficiencies and problems with social interactions. **Binge eating disorder (BED)**, in which binge eating is not followed regularly by any compensatory behaviors (vomiting, laxatives) is a stand-alone category in DSM-5 but shares many features with obesity (see Chapter 47). ED-NOS, often called "disordered eating," can worsen into full syndrome EDs.

EPIDEMIOLOGY

The classic features of AN include a white, early to middle adolescent girl of above-average intelligence and socioeconomic status, who is a conflict-avoidant, risk-aversive, perfectionist struggling with disturbances of anxiety and/or mood. BN tends to emerge in later adolescence, sometimes evolving from AN, and is typified by impulsivity and features of borderline personality disorder that are associated with depression and mood swings. The 0.5-1% and 3-5% incidence rates among younger and older adolescent females for AN and BN, respectively, probably reflect ascertainment bias in sampling and underdiagnosis in cases not fitting the typical profile. The same may be true of the significant gender disparity, in which female patients account for approximately 90% of patients with diagnosed EDs. Ten percent or more of some adolescent female populations have ED-NOS.

No single factor causes the development of an ED; sociocultural studies indicate a complex interplay of culture, ethnicity, gender, peers, and family. The gender dimorphism is presumably related to females having a stronger relationship between body image and self-evaluation, as well as the influence of the Western culture's thin body ideal on the development of EDs. Race and ethnicity appear to moderate the

Table 28-3 DSM-5 Diagnostic Criteria for Avoidant/Restrictive Food Intake Disorder

A. An eating or feeding disturbance (e.g., apparent lack of interest in eating or food; avoidance based on the sensory characteristics of food; concern about aversive consequences of eating) as manifested by persistent failure to meet appropriate nutritional and/or energy needs associated with one (or more) of the following:
   1. Significant weight loss (or failure to achieve expected weight gain or faltering growth in children).
   2. Significant nutritional deficiency.
   3. Dependence on enteral feeding or oral nutritional supplements.
   4. Marked interference with psychosocial functioning.

B. The disturbance is not better explained by lack of available food or by an associated culturally sanctioned practice.

C. The eating disturbance does not occur exclusively during the course of anorexia nervosa or bulimia nervosa, and there is no evidence of a disturbance in the way in which one's body weight or shape is experienced.

D. The eating disturbance is not attributable to a concurrent medical condition or not better explained by another mental disorder. When the eating disturbance occurs in the context of another condition or disorder, the severity of the eating disturbance exceeds that routinely associated with the condition or disorder and warrants additional clinical attention.

Specify if:

In remission: After full criteria for avoidant/restrictive food intake disorder were previously met, the criteria have not been met for a sustained period of time.

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, p. 334.

association between risk factors and disordered eating, with African-American and Caribbean females reporting lower body dissatisfaction and less dieting than Hispanic and non-Hispanic white females. Because peer acceptance is central to healthy adolescent growth and development, especially in early adolescence when AN tends to have its initial prevalence peak, the potential influence of peers on EDs is significant, as are the relationships among peers, body image, and eating. Teasing by peers or by family members (especially male) may be a contributing factor for overweight females.

Family influence in the development of EDs is even more complex because of the interplay of environmental and genetic factors; shared elements of the family environment and immutable genetic factors account for significant (about equal) variance in disordered eating. There are associations between parents' and children's eating behaviors; dieting and physical activity levels suggest parental reinforcement of body-related societal messages. The influence of inherited genetic factors on the emergence of EDs during adolescence is also significant, but not in a direct fashion. Rather, the risk for developing an ED appears to be mediated through a genetic predisposition to anxiety (see Chapter 25), depression (see Chapter 26), or obsessive-compulsive traits that may be modulated through the internal milieu of puberty. There is little evidence that parents "cause" an ED in their child or adolescent; the importance of parents in treatment and recovery cannot be overestimated.

PATHOLOGY AND PATHOGENESIS

The emergence of EDs coinciding with the processes of adolescence (e.g., puberty, identity, autonomy, cognition) indicates the central role of development. A history of sexual trauma is not significantly more common in EDs than in the population at large, but when present it makes recovery more difficult and is more common in BN. EDs may be viewed as a final common pathway, with a number of *predisposing* factors that increase the risk of developing an ED, *precipitating* factors often related to developmental processes of adolescence triggering the emergence of the ED, and *perpetuating* factors that cause an ED to persist. EDs often begin with dieting but gradually progress to unhealthy habits that lessen the negative impact of associated psychosocial problems to which the affected person is vulnerable because of premorbid biologic and psychologic characteristics, family interactions, and social climate. When persistent, the biologic effects of starvation and malnutrition (e.g., true loss of appetite, hypothermia, gastric atony, amenorrhea, sleep disturbance, fatigue, weakness, and depression) combined with the psychologic rewards of increased sense of mastery and reduced emotional reactivity, actually maintain and reward pathologic ED behaviors. This positive reinforcement of behaviors and consequences, generally viewed by parents and others as negative, helps to explain why affected persons characteristically deny that a problem exists and resist treatment. Although noxious, purging can be reinforcing owing to a reduction in anxiety triggered by overeating; purging also can result in short-term, but reinforcing, improvement in mood that is related to changes in neurotransmitters. In addition to an imbalance in neurotransmitters, most notably serotonin and dopamine, there are also alterations in functional anatomy that support the concept of EDs as brain disorders. The cause-and-effect relationship in central nervous system alterations in EDs is not clear, nor is their reversibility.

CLINICAL MANIFESTATIONS

A central feature of EDs is the overestimation of body size, shape or parts (e.g., abdomen, thighs) leading to weight-control practices intended to reduce weight (AN) or prevent weight gain (BN). Associated practices include severe restriction of caloric intake and behaviors intended to reduce the effect of calories ingested, such as compulsive exercising or purging by inducing vomiting or taking laxatives. Eating and weight loss habits commonly found in EDs can result in a wide range of energy intake and output, the balance of which leads to a wide range in weight from extreme loss of weight in AN to fluctuation around a normal to moderately high weight in BN. Reported eating and weight-control habits (Table 28-4) thus inform the initial primary care approach.

Although weight-control patterns guide the initial pediatric approach, an assessment of commonly reported symptoms and findings on physical examination is essential to identify targets for intervention. When reported symptoms of excessive weight loss (feeling tired and cold; lacking energy; orthostasis; difficulty concentrating) are explicitly linked by the clinician to their associated physical signs (hypothermia with acrocyanosis and slow capillary refill, loss of muscle mass, bradycardia with orthostasis), it becomes more difficult for the patient to deny that a problem exists. Furthermore, awareness that bothersome symptoms can be eliminated by healthier eating and activity patterns can increase a patient's motivation to engage in treatment. Tables 28-5 and 28-6 detail common symptoms and signs that should be addressed in a pediatric assessment of a suspected ED.

DIFFERENTIAL DIAGNOSIS

In addition to identifying symptoms and signs that deserve targeted intervention for patients who have an ED or disordered eating, a comprehensive history and physical examination are required in the assessment of a suspected ED to rule out other conditions in the differential diagnosis. Weight loss can occur with any condition in which there is increased catabolism (e.g., malignancy or occult chronic infection) or malabsorption (e.g., inflammatory bowel disease or celiac disease), but these illnesses are generally associated with other findings and are not usually associated with decreased caloric intake. Patients with inflammatory bowel disease can reduce intake to minimize abdominal cramping; eating can cause abdominal discomfort and early satiety in AN because of gastric atony associated with significant weight loss, not malabsorption. Likewise, signs of weight loss in AN might include hypothermia, acrocyanosis with slow capillary refill, and neutropenia suggesting overwhelming sepsis, but the overall picture in EDs is one of relative cardiovascular stability compared to sepsis. Endocrinopathies are also in the differential of EDs. With BN, voracious appetite in the face of weight loss might suggest diabetes mellitus, but blood glucose levels are normal or low in EDs. Adrenal insufficiency mimics

Table 28-4 Eating and Weight Control Habits Commonly Found in Children and Adolescents with an Eating Disorder

	Prominent Feature		Clinical Comments Regarding Eating Disorder Habits	
HABIT	**ANOREXIA NERVOSA**	**BULIMIA NERVOSA**	**ANOREXIA NERVOSA**	**BULIMIA NERVOSA**
Overall intake	Inadequate energy (calories), although volume of food and beverages may be high because of very low caloric density of intake as a result of "diet" and nonfat choices	Variable, but calories normal to high; intake in binges often "forbidden" food or drink that differs from intake at meals	Consistent inadequate caloric intake leading to wasting of the body is an essential feature of diagnosis	Inconsistent balance of intake, exercise and vomiting, but severe caloric restriction is short-lived
Food	Counts and limits calories, especially from fat; Emphasis on "healthy food choices" with reduced caloric density Monotonous, limited "good" food choices, often leading to vegetarian or vegan diet Strong feelings of guilt after eating more than planned leads to exercise and renewed dieting	Aware of calories and fat, but less regimented in avoidance than AN Frequent dieting interspersed with overeating, often triggered by depression, isolation, or anger	Obsessive-compulsive attention to nutritional data on food labels and may have "logical" reasons for food choices in highly regimented pattern, such as sports participation or family history of lipid disorder	Choices less structured, with more frequent diets
Beverages	Water or other low- or no-calorie drinks; nonfat milk	Variable, diet soda common; may drink alcohol to excess	Fluids often restricted to avoid weight gain	Fluids ingested to aid vomiting or replace losses
Meals	Consistent schedule and structure to meal plan Reduced or eliminated caloric content, often starting with breakfast, then lunch, then dinner Volume can increase with fresh fruits, vegetables, and salads as primary food sources	Meals less regimented and planned than in AN; more likely impulsive and unregulated, often eliminated following a binge-purge episode	Rigid adherence to "rules" governing eating leads to sense of control, confidence, and mastery	Elimination of a meal following a binge-purge only reinforces the drive for binge later in the day
Snacks	Reduced or eliminated from meal plan	Often avoided in meal plans, but then impulsively eaten	Snack foods removed early because "unhealthy"	Snack "comfort foods" can trigger a binge
Dieting	Initial habit that becomes progressively restrictive, although often appearing superficially "healthy" Beliefs and "rules" about the patient's idiosyncratic nutritional requirements and response to foods are strongly held	Initial dieting gives way to chaotic eating, often interpreted by the patient as evidence of being "weak" or "lazy"	Distinguishing between healthy meal planning with reduced calories and dieting in ED may be difficult	Dieting tends to be impulsive and short-lived, with "diets" often resulting in unintended weight gain
Binge eating	None in restrictive subtype, but an essential feature in binge-purge subtype	Essential feature, often secretive Shame and guilt prominent afterward	Often "subjective" (more than planned but not large)	Relieves emotional distress, may be planned
Exercise	Characteristically obsessive-compulsive, ritualistic, and progressive May excel in dance, long-distance running	Less predictable May be athletic, or may avoid exercise entirely	May be difficult to distinguish active thin vs. ED	Males often use exercise as means of "purging"
Vomiting	Characteristic of binge-purge subtype May chew, then spit out, rather than swallow, food as a variant	Most common habit intended to reduce effects of overeating Can occur after meal as well as a binge	Physiologic and emotional instability prominent	Strongly "addictive" and self-punishing, but does not eliminate calories ingested—many still absorbed
Laxatives	If used, generally to relieve constipation in restrictive subtype, but as a cathartic in binge-purge subtype	Second most common habit used to reduce or avoid weight gain, often used in increasing doses for cathartic effect	Physiologic and emotional instability prominent	Strongly "addictive," self-punishing, but ineffective means to reduce weight (calories are absorbed in the small intestine, but laxatives work in the colon)
Diet pills	Very rare, if used; more common in binge-purge subtype	Used to either reduce appetite or increase metabolism	Use of diet pills implies inability to control eating	Control over eating may be sought by any means

AN, anorexia nervosa; BN, bulimia nervosa; ED, eating disorder.

Table 28-5 Symptoms Commonly Reported by Patients with an Eating Disorder

SYMPTOMS	Diagnosis: ANOREXIA NERVOSA	Diagnosis: BULIMIA NERVOSA	CLINICAL COMMENTS REGARDING ED SYMPTOMS
Body image	Feels fat, even with extreme emaciation, often with specific body distortions (e.g., stomach, thighs); Strong drive for thinness, with self-efficacy closely tied to appraisal of body shape, size, and/or weight	Variable body image distortion and dissatisfaction, but drive for thinness is less than the desire to avoid gaining weight	Challenging a patient's body image is both ineffective and counter-therapeutic clinically Accepting the patient's expressed body image but noting its discrepancy with symptoms and signs reinforces concept that patient can "feel" fat but also "be" too thin and unhealthy
Metabolism	Hypometabolic symptoms include feeling cold, tired, and weak and lacking energy May be both bothersome and reinforcing	Variable, depending on balance of intake and output and hydration	Symptoms are evidence of body's "shutting down" in an attempt to conserve calories with an inadequate diet Emphasizing reversibility of symptoms with healthy eating and weight gain can motivate patients to cooperate with treatment
Skin	Dry skin, delayed healing, easy bruising, goose flesh Orange-yellow skin on hands	No characteristic symptom, self-injurious behavior may be seen	Skin lacks good blood flow and the ability to heal in low weight Carotenemia with large intake of β-carotene foods; reversible
Hair	Lanugo-type hair growth on face and upper body Slow growth and increased loss of scalp hair	No characteristic symptom	Body hair growth conserves energy Scalp hair loss can worsen during refeeding "telogen effluvium" (resting hair is replaced by growing hair) Reversible with continued healthy eating
Eyes	No characteristic symptom	Subconjunctival hemorrhage	Caused by increased intrathoracic pressure during vomiting
Teeth	No characteristic symptom	Erosion of dental enamel erosion Decay, fracture, and loss of teeth	Intraoral stomach acid resulting from vomiting etches dental enamel, exposing softer dental elements
Salivary glands	No characteristic symptom	Enlargement (no to mild tenderness)	Caused by chronic binge eating and induced vomiting, with parotid enlargement more prominent than submandibular; reversible
Heart	Dizziness, fainting in restrictive subtype Palpitations more common in binge-purge subtype	Dizziness, fainting, palpitations	Dizziness and fainting due to postural orthostatic tachycardia and dysregulation at hypothalamic and cardiac level with weight loss, as a result of hypovolemia with binge-purge Palpitations and arrhythmias often caused by electrolyte disturbance Symptoms reverse with weight gain and/or cessation of binge-purge
Abdomen	Early fullness and discomfort with eating Constipation Perceives contour as "fat," often preferring well-defined abdominal musculature	Discomfort after a binge Cramps and diarrhea with laxative abuse	Weight loss is associated with reduced volume and tone of GI tract musculature, especially the stomach Laxatives may be used to relieve constipation or as a cathartic Symptom reduction with healthy eating can take weeks to occur
Extremities and musculoskeletal	Cold, blue hands and feet	No characteristic symptoms Self-cutting or burning on wrists or arms	Energy-conserving low body temperature with slow blood flow most notable peripherally Quickly reversed with healthy eating
Nervous system	No characteristic symptom	No characteristic symptom	Neurologic symptoms suggest a diagnosis other than an ED
Mental status	Depression, anxiety, obsessive-compulsive symptoms, alone or in combination	Depression; PTSD; borderline personality disorder traits	Underlying mood disturbances can worsen with dysfunctional weight control practices and can improve with healthy eating AN patients might report emotional "numbness" with starvation, preferable to emotionality associated with healthy eating

AN, anorexia nervosa; BN, bulimia nervosa; ED, eating disorder; GI, gastrointestinal; PTSD, posttraumatic stress disorder.

Table 28-6 Signs Commonly Found in Patients with Eating Disorders Relative to Prominent Feature of Weight Control

PHYSICAL SIGN	Prominent Feature: RESTRICTIVE INTAKE	Prominent Feature: BINGE EATING/PURGING	CLINICAL COMMENTS RELATED TO EATING DISORDER SIGNS
General appearance	Thin to cachetic, depending on balance of intake and output Might wear bulky clothing to hide thinness and might resist being examined	Thin to overweight, depending on the balance of intake and output through various means	Examine in hospital gown Weight loss more rapid with reduced intake and excessive exercise Binge eating can result in large weight gain, regardless of purging behavior Appearance depends on balance of intake and output and overall weight control habits
Weight	Low and falling (if previously overweight may be normal or high); may be falsely elevated if patient drinks fluids or adds weights to body before being weighed	Highly variable, depending on balance of intake and output and state of hydration Falsification of weight is unusual	Weigh in hospital gown with no underwear, after voiding (measure urine SG) Remain in gown until physical exam completed to identify possible fluid loading (low urine SG, palpable bladder) or adding weights to body
Metabolism	Hypothermia: temp < 35.5°C (95.9°F), pulse < 60 beats/min Slowed psychomotor response with very low core temperature	Variable, but hypometabolic state is less common than in AN	Hypometabolism related to disruption of hypothalamic control mechanisms as a result of weight loss Signs of hypometabolism (cold skin, slow capillary refill, acrocyanosis) most evident in hands and feet, where energy conservation is most active
Skin	Dry Increased prominence of hair follicles Orange or yellow hands	Calluses over proximal knuckle joints of hand (Russell's sign)	Carotenemia with large intake of β-carotene foods Russell's sign: maxillary incisors abrasion develops into callus with chronic digital pharyngeal stimulation, usually on dominant hand
Hair	Lanugo-type hair growth on face and upper body Scalp hair loss, especially prominent in parietal region	No characteristic sign	Body hair growth conserves energy Scalp hair loss "telogen effluvium" can worsen weeks after refeeding begins, as hair in resting phase is replaced by growing hair
Eyes	No characteristic sign	Subconjunctival hemorrhage	Increased intrathoracic pressure during vomiting
Teeth	No characteristic sign	Eroded dental enamel and decayed, fractured, missing teeth	Perimolysis, worse on lingual surfaces of maxillary teeth, is intensified by brushing teeth without preceding water rinse
Salivary glands	No characteristic sign	Enlargement, relatively nontender	Parotid > submandibular involvement with frequent and chronic binge eating and induced vomiting
Throat	No characteristic sign	Absent gag reflex	Extinction of gag response with repeated pharyngeal stimulation
Heart	Bradycardia, hypotension, and orthostatic pulse differential > 25 beats/min	Hypovolemia if dehydrated	Changes in AN resulting from central hypothalamic and intrinsic cardiac function Orthostatic changes less prominent if athletic, more prominent if associated with purging
Abdomen	Scaphoid, organs may be palpable but not enlarged, stool-filled left lower quadrant	Increased bowel sounds if recent laxative use	Presence of organomegaly requires investigation to determine cause Constipation prominent with weight loss
Extremities and musculoskeletal system	Cold, acrocyanosis, slow capillary refill Edema of feet Loss of muscle, subcutaneous, and fat tissue	No characteristic sign, but may have rebound edema after stopping chronic laxative use	Signs of hypometabolism (cold) and cardiovascular dysfunction (slow capillary refill and acrocyanosis) in hands and feet Edema, caused by capillary fragility more than hypoproteinemia in AN, can worsen in early phase of refeeding
Nervous system	No characteristic sign	No characteristic sign	Water loading before weigh-ins can cause acute hyponatremia
Mental status	Anxiety about body image, irritability, depressed mood, oppositional to change	Depression, evidence of PTSD, more likely suicidal than AN	Mental status often improves with healthier eating and weight; SSRIs only shown to be effective for BN

AN, anorexia nervosa; BN, bulimia nervosa; PTSD, posttraumatic stress disorder; SG, specific gravity; SSRI, selective serotonin reuptake inhibitor.

many physical symptoms and signs found in restrictive AN but is associated with elevated potassium levels and hyperpigmentation. Although thyroid disorders are often considered, because of changes in weight and other symptoms in AN, the overall presentation includes symptoms of both underactive and overactive thyroid, such as hypothermia, bradycardia, and constipation, as well as weight loss and excessive physical activity, respectively.

In the central nervous system, craniopharyngiomas and Rathke pouch tumors can mimic some of the findings of AN, such as weight loss and growth failure, and even some body image disturbances, but the latter are less fixed than in typical EDs and are associated with other findings, including evidence of increased intracranial pressure. Mitochondrial neurogastrointestinal encephalomyopathy, caused by a mutation in the *TYMP* gene, presents with gastrointestinal dysmotility, cachexia, ptosis, peripheral neuropathy, ophthalmoplegia, and leukoencephalopathy. Symptoms begin during the second decade of life and are often initially diagnosed as AN. Early satiety, vomiting, cramps, constipation, and pseudoobstruction result in weight loss often before the neurologic features are noticed.

Any patient with an atypical presentation of an ED, based on age, sex, or other factors not typical for AN or BN deserves a scrupulous search for an alternative explanation. Patients can have both an underlying illness and an ED. The core features of dysfunctional eating habits—body image disturbance and change in weight—can coexist with conditions such as diabetes mellitus, where patients might manipulate their insulin dosing to lose weight.

LABORATORY FINDINGS

Because the diagnosis of an ED is made clinically, there is no confirmatory laboratory test. Laboratory abnormalities, when found, are the result of malnutrition, weight-control habits used, or medical complications; studies should be chosen based on history and physical examination. A routine screening battery typically includes complete blood count, erythrocyte sedimentation rate (should be normal), and biochemical profile. Common abnormalities in ED include low white blood cell count with normal hemoglobin and differential; hypokalemic, hypochloremic metabolic alkalosis with severe vomiting; mildly elevated liver enzymes, cholesterol, and cortisol levels; low gonadotropins and blood glucose with marked weight loss; and generally normal total protein, albumin, and renal function. An electrocardiogram may be useful when profound bradycardia or arrhythmia is detected; the electrocardiogram usually has low voltage, with nonspecific ST or T wave changes. Although prolonged QTc has been reported, prospective studies have not found an increased risk for this.

COMPLICATIONS

No organ is spared the harmful effects of dysfunctional weight-control habits, but the most concerning targets of medical complications are the heart, brain, gonads, and bones. Some **heart** findings in EDs (e.g., sinus bradycardia and hypotension) are *physiologic* adaptations to starvation that conserve calories and reduce afterload. Cold, blue hands and feet with slow capillary refill that can result in tissue perfusion insufficient to meet demands also represent energy-conserving responses associated with inadequate intake. All of these acute changes are reversible with restoration of nutrition and weight. Significant orthostatic pulse changes, prolonged corrected QT interval, ventricular dysrhythmias, or reduced myocardial contractility reflect myocardial impairment that can be lethal. In addition, with extremely low weight, **refeeding syndrome** (a result of the rapid drop in serum phosphorous, magnesium, and potassium with excessive reintroduction of calories, especially carbohydrates), is associated with acute heart failure and neurologic symptoms. With long-term malnutrition, the myocardium appears to be more prone to tachyarrhythmias, the second most common cause of death after suicide. In BN, dysrhythmias can also be related to electrolyte imbalance.

Clinically, the primary **brain** area affected acutely in EDs, especially with weight loss, is the hypothalamus. Hypothalamic dysfunction is reflected in problems with thermoregulation (warming and cooling), satiety, sleep, autonomic cardioregulatory imbalance (orthostasis), and endocrine function (reduced gonadal and excessive adrenal cortex stimulation), all of which are reversible. Anatomic studies of the brain in ED have focused on AN, with the most common finding being increased ventricular and sulcal volumes that normalize with weight restoration. Persistent gray-matter deficits following recovery, related to the degree of weight loss, have been reported. Elevated medial temporal lobe cerebral blood flow on positron emission tomography similar to that found in psychotic patients, suggests that these changes may be related to body image distortion. Also, visualizing high-calorie foods is associated with exaggerated responses in the visual association cortex that are similar to those seen in patients with specific phobias. Patients with AN might have an imbalance between serotonin and dopamine pathways related to neurocircuits in which dietary restraint reduces anxiety.

Reduced **gonadal** function occurs in male and female patients; it is clinically manifested in AN as amenorrhea in female patients and erectile dysfunction in males. It is related to understimulation from the hypothalamus as well as cortical suppression related to physical and emotional stress. Amenorrhea precedes significant dieting and weight loss in up to 30% of females with AN, and most adolescents with EDs perceive the absence of menses positively. The primary health concern is the negative effect of decreased ovarian function and estrogen on **bones**. Decreased bone mineral density (BMD) with osteopenia or the more severe osteoporosis is a significant complication of EDs (more pronounced in AN than BN). Data do not support the use of sex hormone replacement therapy because this alone does not improve other causes of low BMD (low body weight, lean body mass, and insulin-like growth factor-1; high cortisol).

TREATMENT

Principles Guiding Primary Care Treatment

The approach in primary care should facilitate the acceptance by the patient (and parents) of the diagnosis and initial treatment recommendations. A **nurturant–authoritative** approach using the **biopsychosocial** model is useful. A pediatrician who explicitly acknowledges that the patient may disagree with the diagnosis and treatment recommendations and be ambivalent about changing eating habits, while also acknowledging that recovery requires strength, courage, will-power and determination, demonstrates *nurturance*. Parents also find it easier to be nurturant once they learn that the development of an ED is neither a willful decision by the patient nor a reflection of bad parenting. Framing the ED as a coping mechanism for a complex variety of issues with both positive and negative aspects avoids blame or guilt and can prepare the family for professional help that will focus on strengths and restoring health, rather than on the deficits in the adolescent or the family.

The **authoritative** aspect of a physician's role comes from expertise in health, growth, and physical development. A goal of primary care treatment should be attaining and maintaining health—not merely weight gain—although weight gain is a means to the goal of wellness. Providers who frame themselves as consultants to the patient with *authoritative* knowledge about health can avoid a countertherapeutic authoritarian stance. Primary care health-focused activities include monitoring the patient's physical status, setting limits on behaviors that threaten the patient's health, involving specialists with expertise in EDs on the treatment team, and continuing to provide primary care for health maintenance, acute illness, or injury.

The **biopsychosocial** model uses a broad ecologic framework, starting with the biologic impairments of physical health related to dysfunctional weight control practices, evidenced by symptoms and signs. Explicitly linking ED behaviors to symptoms and signs can increase motivation to change. In addition, there are usually unresolved psychosocial conflicts in both the intrapersonal (self-esteem, self-efficacy) and interpersonal (family, peers, school) domains. Weight-control practices initiated as coping mechanisms become reinforced because of positive feedback. That is, external rewards (e.g., compliments about improved physical appearance) and internal rewards (e.g., perceived mastery over what is eaten or what is done to minimize the effects of overeating through exercise or purging) are more powerful to maintain

behavior than negative feedback (e.g., conflict with parents, peers, and others about eating) is to change it. Thus, when definitive treatment is initiated, more productive alternative means of coping must be developed.

Nutrition and Physical Activity

The primary care provider generally begins the process of prescribing nutrition, although a dietitian should be involved eventually in the meal planning and nutritional education of patients with AN or BN. Framing food as fuel for the body and the source of energy for daily activities emphasizes the health goal of increasing the patient's energy level, endurance, and strength. For patients with AN and low weight, the nutrition prescription should work toward gradually increasing weight at the rate of about 0.5-1 lb/wk, by increasing energy intake by 100-200 kcal increments every few days toward a target of approximately 90% of average body weight for sex, height, and age. Weight gain will not occur until intake exceeds output, and eventual intake for continued weight gain can exceed 4,000 kcal/day, especially for patients who are anxious and have high levels of thermogenesis from nonexercise activity. Stabilizing intake is the goal for patients with BN, with a gradual introduction of forbidden foods while also limiting foods that might trigger a binge.

When initiating treatment of an ED in a primary care setting, the clinician should be aware of common cognitive patterns. Patients with AN typically have all-or-none thinking (related to perfectionism) with a tendency to overgeneralize and jump to catastrophic conclusions, while assuming that their body is governed by rules that do not apply to others. These tendencies lead to the dichotomization of foods into good or bad categories, having a day ruined because of 1 unexpected event, or choosing foods based on rigid self-imposed restrictions. These thoughts may be related to neurocircuitry and neurotransmitter abnormalities related to executive function and rewards.

A standard nutritional balance of 15-20% calories from protein, 50-55% from carbohydrate, and 25-30% from fat is appropriate. The fat content may need to be lowered to 15-20% early in the treatment of AN because of continued fat phobia. With the risk of low BMD in patients with AN, calcium and vitamin D supplements are often needed to attain the recommended 1,300 mg/day intake of calcium. Refeeding can be accomplished with frequent small meals and snacks consisting of a variety of foods and beverages (with minimal diet or fat-free products), rather than fewer high-volume high-calorie meals. Some patients find it easier to take in part of the additional nutrition as canned supplements (medicine) rather than food. Regardless of the source of energy intake, the risk for refeeding syndrome (acute tachycardia and heart failure with neurologic symptoms associated primarily with acute decline in serum phosphate and magnesium) increases with the degree of weight loss and the rapidity of caloric increases. Therefore, if the weight has fallen below 80% of expected weight for height, refeeding should proceed cautiously, possibly in the hospital (Table 28-7).

Patients with AN tend to have a highly structured day with restrictive intake, in contrast to BN, which is characterized by a lack of structure, resulting in chaotic eating patterns and binge-purge episodes. All patients with AN, BN, or ED-NOS benefit from a daily structure for healthy eating that includes 3 meals and at least 1 snack a day, distributed evenly over the day, based on balanced meal planning. Breakfast deserves special emphasis because it is often the first meal eliminated in AN and is often avoided the morning after a binge-purge episode in BN. In addition to structuring meals and snacks, patients should plan structure in their activities. Although overexercising is common in AN, completely prohibiting exercise can lead to further restriction of intake or to surreptitious exercise; inactivity should be limited to situations in which weight loss is dramatic or there is physiologic instability. Also, healthy exercise (once a day, for no more than 30 minutes, at no more than moderate intensity) can improve mood and make increasing calories more acceptable. Because patients with AN often are unaware of their level of activity and tend toward progressively increasing their output, exercising without either a partner or supervision is not recommended.

Table 28-7	Indications for Inpatient Medical Hospitalization of Patients with Anorexia Nervosa
PHYSICAL AND LABORATORY	
Heart rate < 50 beats/min	
Other cardiac rhythm disturbances	
Blood pressure < 80/50 mm Hg	
Postural hypotension resulting in a >10 mm Hg drop or a >25 beats/min increase	
Hypokalemia	
Hypophosphatemia	
Hypoglycemia	
Dehydration	
Body temperature < 36.1°C (97°F)	
<80% healthy body weight	
Hepatic, cardiac, or renal compromise	
PSYCHIATRIC	
Suicidal intent and plan	
Very poor motivation to recover (in family and patient)	
Preoccupation with ego-syntonic thoughts	
Coexisting psychiatric disorders	
MISCELLANEOUS	
Requires supervision after meals and while using the restroom	
Failed day treatment	

Primary Care Treatment

Follow-up primary care visits are essential in the management of EDs; close monitoring of the response of the patient and the family to suggested interventions is required to determine which patients can remain in primary care treatment (patients with early, mildly disordered eating), which patients need to be referred to individual specialists for co-management (mildly progressive disordered eating), and which patients need to be referred for interdisciplinary team management (EDs). Between the initial and subsequent visits, the patient can record daily caloric intake (food, drink, amount, time, location), physical activity (type, duration, intensity), and emotional state (e.g., angry, sad, worried) in a journal that is reviewed jointly with the patient in follow-up. Focusing on the recorded data helps the clinician to identify dietary and activity deficiencies and excesses as well as behavioral and mental health patterns, and the patient to become objectively aware of the relevant issues to address in recovery.

Given the tendency of patients with AN to overestimate their caloric intake and underestimate their activity level, before reviewing the journal record it is important at each visit to measure weight, without underwear, in a hospital gown after voiding; urine specific gravity; temperature; and blood pressure and pulse in supine, sitting, and standing positions as objective data. In addition, a targeted physical examination focused on hypometabolism, cardiovascular stability, and mental status, as well as any related symptoms, should occur at each visit to monitor progress (or regression).

Referral to Mental Health Services

In addition to referral to a registered dietitian, mental health services are an important element of treatment of EDs. Depending on availability and experience, these services can be provided by a psychiatric social worker, psychologist, or psychiatrist, who should team with the primary care provider. Although patients with AN often are prescribed a selective serotonin reuptake inhibitor (SSRI) because of depressive symptoms, there is no evidence of efficacy for patients at low weight; food remains the initial treatment of choice to treat depression in AN. SSRIs, very effective in reducing binge-purge behaviors regardless of depression, are considered a standard element of therapy in BN. SSRI dosage in BN, however, may need to increase to an equivalent of more than 60 mg of fluoxetine to maintain effectiveness.

Cognitive-behavioral therapy, which focuses on restructuring "thinking errors" and establishing adaptive patterns of behavior, is more effective than interpersonal or psychoanalytic approaches.

Dialectical behavioral therapy, in which distorted thoughts and emotional responses are challenged, analyzed, and replaced with healthier ones, with an emphasis on "mindfulness," requires adult thinking skills and is useful for older patients with BN. **Group therapy** can provide much needed support, but it requires a skilled clinician. Combining patients at various levels of recovery who experience variable reinforcement from dysfunctional coping behaviors can be challenging if group therapy patients compete with each other to be "thinner" or take up new behaviors such as vomiting.

The younger the patient, the more intimately the parents need to be involved in therapy. The only treatment approach with evidence-based effectiveness in the treatment of AN in children and adolescents is **family-based treatment**, exemplified by the Maudsley approach. This 3-phase intensive outpatient model helps parents play a positive role in restoring their child's eating and weight to normal, then returns control of eating to the child who has demonstrated the ability to maintain healthy weight, and then encourages healthy progression in the other domains of adolescent development. Features of effective family treatment include an agnostic approach in which the cause of the disease is unknown and irrelevant to weight gain, emphasizing that parents are *not* to blame for EDs; parents being actively nurturing and supportive of their child's healthy eating while reinforcing limits on dysfunctional habits, rather than an authoritarian food police or complete hands-off approach; and reinforcement of parents as the best resource for recovery for almost all patients, with professionals serving as consultants and advisors to help parents address challenges.

Referral to an Interdisciplinary Eating Disorder Team

The treatment of a child or adolescent diagnosed with an ED is ideally provided by an interdisciplinary team (physician, nurse, dietitian, mental health provider) with expertise treating pediatric patients. Because such teams, often led by specialists in adolescent medicine at medical centers, are not widely available, the primary care provider might need to convene such a team. Adolescent medicine–based programs report encouraging treatment outcomes, possibly related to patients entering earlier into care and the stigma that some patients and parents may associate with psychiatry-based programs. Specialty centers focused on treating EDs are generally based in psychiatry and often have separate tracks for younger and adult patients. The elements of treatment noted earlier (cognitive-behavioral therapy, dialectical behavioral therapy, and family-based therapy), as well as individual and group treatment should all be available as part of interdisciplinary team treatment. Comprehensive services ideally include intensive outpatient and/or partial hospitalization as well as inpatient treatment. Regardless of the intensity, type, or location of the treatment services, the patient, parents, and primary care provider are essential members of the treatment team. A recurring theme in effective treatment is helping patients and families re-establish connections that are disrupted by the ED.

Inpatient medical treatment of EDs is generally limited to patients with AN, to stabilize and treat life-threatening starvation and to provide supportive mental health services. Inpatient medical care may be required to avoid refeeding syndrome in severely malnourished patients, provide nasogastric tube feeding for patients unable or unwilling to eat, or initiate mental health services, especially family-based treatment, if this has not occurred on an outpatient basis (see Table 28-7). Admission to a general pediatric or hospital unit is advised only for short-term stabilization in preparation for transfer to a medical unit with expertise in treating pediatric EDs. Inpatient psychiatric care of EDs should be provided on a unit with expertise in managing the often challenging behaviors (e.g., hiding or discarding food, vomiting, surreptitious exercise) and emotional problems (e.g., depression, anxiety). Suicidal risk is small, but patients with AN might threaten suicide if made to eat or gain weight in an effort to get their parents to back off.

An ED **partial hospital program** offers outpatient services that are less intensive than round-the-clock inpatient care. Generally held 4-5 days a wk for 6 to 9 hr each session, partial hospital program services typically are group-based and include eating at least 2 meals as well as opportunities to address issues in a setting that more closely approximates "real life" than inpatient treatment. That is, patients sleep at home and are free-living on weekends, exposing them to challenges that can be processed during the 25-40 hr in program, also sharing group and family experiences.

Supportive Care

In relation to pediatric EDs, support groups are primarily designed for parents. Because their daughter or son with an ED often resists the diagnosis and treatment, parents often feel helpless and hopeless. Because of the historical precedent of blaming parents for causing EDs, parents often express feelings of shame and isolation (www.maudsleyparents.org). Support groups and multifamily therapy sessions bring parents together with other parents whose families are at various stages of recovery from an ED in ways that are educational and encouraging. Patients often benefit from support groups after intensive treatment or at the end of treatment because of residual body image or other issues after eating and weight have normalized.

PROGNOSIS

With early diagnosis and effective treatment, 80% or more of youth with AN recover: They develop normal eating and weight control habits, resume menses, maintain average weight for height, and function in school, work, and relationships, although some still have poor body image. With weight restoration, fertility returns as well, although the weight for resumption of menses (approximately 92% of average body weight for height) may be lower than the weight for ovulation. The prognosis for BN is less-well established, but outcome improves with multidimensional treatment that includes SSRIs and attention to mood, past trauma, impulsivity, and any existing psychopathology. Atypical AN and ED-NOS may still have significant morbidity.

PREVENTION

Given the complexity of the pathogenesis of EDs, prevention is difficult. Targeted preventive interventions can reduce risk factors in older adolescents and college-age women. Universal prevention efforts to promote healthy weight regulation and discourage unhealthy dieting have not shown effectiveness in middle-school students. Programs that include recovered patients or focus on the problems associated with EDs can inadvertently normalize or even glamorize EDs and should be discouraged.

Chapter 29

Disruptive, Impulse-Control, and Conduct Disorders

Heather J. Walter, Asma Rashid, Lovern R. Moseley, and David R. DeMaso

The disruptive, impulse-control, and conduct disorders are interrelated sets of psychiatric symptoms characterized by a core deficit in self-regulation of anger, aggression, defiance, and antisocial behaviors. The disruptive, impulse-control, and conduct disorders include oppositional defiant, intermittent explosive, conduct, other specified/unspecified disruptive, impulse control, and conduct, and antisocial personality disorders, as well as pyromania and kleptomania.

Table 29-1 DSM-5 Diagnostic Criteria for Oppositional Defiant Disorder

A. A pattern of angry/irritable mood, argumentative/defiant behavior, or vindictiveness lasting at least 6 mo as evidenced by at least 4 symptoms from any of the following categories, and exhibited during interaction with at least 1 individual who is not a sibling.

Angry/Irritable Mood

1. Often loses temper.
2. Is often touchy or easily annoyed.
3. Is often angry and resentful.

Argumentative/Defiant Behavior

4. Often argues with authority figures or, for children and adolescents, with adults.
5. Often actively defies or refuses to comply with requests from authority figures or with rules.
6. Often deliberately annoys others.
7. Often blames others for his or her mistakes or misbehavior.

Vindictiveness

8. Has been spiteful or vindictive at least twice within the past 6 mo.

Note: The persistence and frequency of these behaviors should be used to distinguish a behavior that is within normal limits from a behavior that is symptomatic. For children younger than 5 yr, the behavior should occur on most days for a period of at least 6 mo unless otherwise noted (Criterion A8). For individuals 5 yr or older, the behavior should occur at least once per week for at least 6 mo, unless otherwise noted (Criterion A8). While these frequency criteria provide guidance on a minimal level of frequency to define symptoms, other factors should be considered, such as whether the frequency and intensity of the behaviors are outside a range that is normative for the individual's developmental level, gender, and culture.

B. The disturbance in behavior is associated with distress in the individual or others in his or her immediate social context (e.g., family, peer group, work colleagues), or it impacts negatively on social, educational, occupational, or other important areas of functioning.

C. The behaviors do not occur exclusively during the course of a psychotic, substance use, depressive, or bipolar disorder. Also, the criteria are not met for disruptive mood dysregulation disorder.

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, pp. 462–463.

Table 29-2 DSM-5 Diagnostic Criteria for Intermittent Explosive Disorder

A. Recurrent behavioral outbursts representing a failure to control aggressive impulses as manifested by either of the following:
   1. Verbal aggression (e.g., temper tantrums, tirades, verbal arguments or fights) or physical aggression toward property, animals, or other individuals, occurring twice weekly, on average, for a period of 3 mo. The physical aggression does not result in damage or destruction of property and does not result in physical injury to animals or other individuals.
   2. Three behavioral outbursts involving damage or destruction of property and/or physical assault involving physical injury against animals or other individuals occurring with a 12-mo period.

B. The magnitude of aggressiveness expressed during the recurrent outbursts is grossly out of proportion to the provocation or to any precipitating psychosocial stressors.

C. The recurrent aggressive outbursts are not premeditated (i.e., they are impulsive and/or anger-based) and are not committed to achieve some tangible objective (e.g., money, power, intimidation).

D. The recurrent aggressive outbursts cause either marked distress in the individual or impairment in occupational or interpersonal functioning, or as associated with financial or legal consequences.

E. Chronological age is at least 6 yr (or equivalent developmental level).

F. The recurrent aggressive outbursts are not better explained by another mental disorder (e.g., major depressive disorder, bipolar disorder, disruptive mood dysregulation disorder, a psychotic disorder, antisocial personality disorder, borderline personality disorder) and are not attributable to another medical condition (e.g., head trauma, Alzheimer disease) or to the physiologic effects of a substance (e.g., a drug of abuse, a medication). For children ages 6-18 yr, aggressive behavior that occurs as part of an adjustment disorder should not be considered for this diagnosis.

Note: This diagnosis can be made in addition to the diagnosis of attention-deficit/hyperactivity disorder, conduct disorder, oppositional defiant disorder, or autism spectrum disorder when recurrent impulsive aggressive outbursts are in excess of those usually seen in these disorders and warrant clinical attention.

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, p. 466.

DESCRIPTION

Oppositional defiant disorder (**ODD**) is characterized by a pattern lasting at least 6 mo of angry, irritable mood, argumentative/defiant behavior, or vindictiveness exhibited during interaction with at least 1 individual who is not a sibling (Table 29-1). For preschool children, the behavior must occur on most days whereas in school-age children, the behavior must occur at least once a week. The severity of the disorder is considered to be mild if symptoms are confined to only 1 setting (e.g., at home, at school, at work, with peers), moderate if symptoms are present in at least 2 settings, and severe if symptoms are present in 3 or more settings.

Intermittent explosive disorder (**IED**) is characterized by recurrent verbal or physical aggression that is grossly disproportionate to the provocation or to any precipitating psychosocial stressors (Table 29-2). The outbursts, which are impulsive and/or anger-based rather than premeditated and/or instrumental, typically last for less than 30 min and commonly occur in response to a minor provocation by a close intimate.

Conduct disorder (**CD**) is characterized by a repetitive and persistent pattern over at least 12 mo of serious rule-violating behavior in which the basic rights of others or major societal norms or rules are violated (Table 29-3). The symptoms of CD are divided into 4 major categories: *aggression to people and animals*, *destruction of property*, *deceitfulness or theft*, and *serious rule violations* (e.g., truancy, running away). Three subtypes of CD (which have different prognostic significance) are based on the age of onset: *childhood-onset type*, *adolescent onset type*, and *unspecified*. A small proportion of individuals with CD exhibit characteristics (lack of remorse/guilt, callous/lack of empathy, unconcerned about performance, shallow/deficient affect) that qualify for the "*with limited prosocial emotions*" specifier. CD is classified as mild if few if any symptoms in excess of those required for the diagnosis are present, and the symptoms cause relatively minor harm to others. CD is classified as severe if many symptoms in excess of those required for the diagnosis are present, and the symptoms cause considerable harm to others. Moderate severity is intermediate between mild and severe.

Other specified/unspecified disruptive, impulse-control, and CD (subsyndromal disorder) applies to presentations in which symptoms characteristic of the disorders in this class are present and cause clinically significant distress or functional impairment, but do not meet full diagnostic criteria for any of the disorders in this class.

EPIDEMIOLOGY

The prevalence of ODD approximates 3% and in preadolescents is more common in males than females (1.4 : 1). One-year prevalence rates for IED and CD approximate 3% and 4%, respectively. For CD, prevalence rates rise from childhood to adolescence and are higher

Table 29-3 DSM-5 Diagnostic Criteria for Conduct Disorder

A. A repetitive and persistent pattern of behavior in which the basic rights of others or major age-appropriate societal norms or rules are violated, as manifested by the presence of at least 3 of the following 15 criteria in the past 12 mo from any of the categories below, with at least 1 criterion present in the past 6 mo:

Aggression to People and Animals

1. Often bullies, threatens, or intimidates others.
2. Often initiates physical fights.
3. Has used a weapon that can cause serious physical harm to others (e.g., a bat, brick, broken bottle, knife, gun).
4. Has been physically cruel to people.
5. Has been physically cruel to animals.
6. Has stolen while confronting a victim (e.g., mugging, purse snatching, extortion, armed robbery).
7. Has forced someone into sexual activity.

Destruction of Property

8. Has deliberately engaged in fire setting with the intention of causing serious damage.
9. Has deliberately destroyed others' property (other than by fire setting).

Deceitfulness or Theft

10. Has broken into someone else's house, building, or car.
11. Often lies to obtain good or favors or to avoid obligations (i.e., "cons" others).
12. Has stolen items of nontrivial value without confronting a victim (e.g., shoplifting, but without breaking and entering; forgery).

Serious Violations of Rules

13. Often stays out at night despite parental prohibitions, beginning before age 13 yr.
14. Has run away from home overnight at least twice while living in the parental or parental surrogate home, or once without returning for a lengthy period.
15. Is often truant from school, beginning before age 13 yr.

B. The disturbance in behavior causes clinically significant impairment in social, academic, or occupational functioning.

C. If the individual is age 18 yr or older, criteria are not met for antisocial personality disorder.

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, pp. 469–471.

among males than among females. The prevalence of these disorders has been shown to be higher in lower socioeconomic classes.

CLINICAL COURSE

Oppositional behavior can occur in all children and adolescents from time to time, particularly during the toddler and early teenage periods when autonomy and independence are normative developmental tasks. Oppositional behavior becomes a concern when it is intense, persistent, and pervasive and when it affects the child's social, family, and academic life.

Some of the earliest manifestations of oppositionality are stubbornness (3 yr), defiance and temper tantrums (4-5 yr), and argumentativeness (6 yr). Approximately 65% of children with ODD exit from the diagnosis after a 3 yr follow-up; earlier age at onset of oppositional symptoms conveys a poorer prognosis. ODD often precedes the development of CD (approximately 30% higher likelihood with comorbid attention-deficit/hyperactivity disorder [ADHD; see Chapter 33]), but also increases the risk for the development of depressive and anxiety disorders. The defiant and vindictive symptoms carry most of the risk for CD, whereas the angry-irritable mood symptoms carry most of the risk for anxiety and depression.

IED most commonly begins in late childhood or adolescence and appears to follow a chronic and persistent course over many years.

The onset of CD may occur as early as the preschool years, but the first significant symptoms usually emerge during the period from middle childhood through middle adolescence; onset is rare after age 16 yr. Symptoms of CD vary with age as the individual develops increased physical strength, cognitive abilities, and sexual maturity. Symptoms that emerge first tend to be less serious (e.g., lying), while those emerging later tend to be more severe (e.g., sexual or physical assault). Severe behaviors emerging at an early age convey a poor prognosis. In the majority of individuals, the disorder remits by adulthood; in a substantial fraction, antisocial personality disorder develops. Individuals with CD also are at risk for the later development of mood, anxiety, posttraumatic stress, impulse control, psychotic, somatic symptom, and substance-related disorders.

DIFFERENTIAL DIAGNOSIS

The disorders in this diagnostic class share a number of characteristics with each other as well as with disorders from other classes, and as such must be carefully differentiated. ODD can be distinguished from CD by the absence of physical aggression and destructiveness, and by the presence of angry/irritable mood; ODD can be distinguished from IED by the lack of serious aggression (physical assault). IED can be distinguished from CD by the lack of predatory aggression and other nonaggressive symptoms of CD.

The oppositionality seen in ODD must be distinguished from that seen in ADHD, depressive and bipolar disorders (including ***disruptive mood dysregulation disorder*** [see Chapter 26]), language disorders and intellectual disability, and social anxiety disorder. ODD should not be diagnosed if the behaviors occur exclusively during the course of a psychotic, substance use, depressive or bipolar disorder, and if criteria are met for disruptive mood dysregulation disorder. IED should not be diagnosed if the behavior can be better explained by a depressive, bipolar, disruptive mood dysregulation, psychotic, antisocial personality, or borderline personality disorder. The aggression seen in CD must be distinguished from that seen in ADHD and intermittent explosive, depressive, bipolar, and adjustment disorders.

COMORBIDITY

Rates of ODD are much higher in children with ADHD, which suggests shared temperamental risk factors. Depressive, anxiety, and substance use disorders are most commonly comorbid with IED. ADHD and ODD are both common in individuals with CD, and this comorbid presentation predicts worse outcomes. CD also may co-occur with anxiety, depressive, bipolar, learning, language, and substance-related disorders.

SEQUELAE

The disruptive, impulse-control, and CDs are associated with a wide range of psychiatric disorders in adulthood and with many other adverse outcomes, such as suicidal behavior, physical injury, delinquency and criminality, legal problems, substance use, unplanned pregnancy, social instability, marital failure, and academic and occupational underachievement.

ETIOLOGY AND RISK FACTORS

At the individual level, a number of neurobiologic markers (lower heart rate and skin conductance reactivity, reduced basal cortisol reactivity, abnormalities in the prefrontal cortex and amygdala, serotonergic abnormalities) have been variously associated with aggressive behavior disorders. Other biologic risk factors include pre-, peri-, and postnatal insults, cognitive and linguistic impairment (particularly language-based learning deficits); difficult temperamental characteristics (particularly negative affectivity, poor frustration tolerance, impulsivity); certain personality characteristics (novelty seeking, reduced harm avoidance, and reward dependence); and certain cognitive characteristics (cognitive rigidity, hostile attributions for ambiguous social cues).

At the family level, a consistently demonstrated risk factor is ineffective parenting. Parents of behaviorally disordered children have been found to be more inconsistent in their use of rules; to issue more and unclear commands; to be more likely to respond to their child on the basis of their mood rather than the child's behavior; to be less

Table 29-4 Anger/Aggression-Specific Screening Instruments

NAME OF INSTRUMENT	INFORMANT(S)	AGE RANGE	NUMBER OF ITEMS
Children's Aggression Scale	Parent, Teacher	5-18 y	33 (P), 23 (T)
Eyberg Child Behavior Inventory	Parent	2-16 y	36
Outburst Monitoring Scale	Parent	12-17 y	20
Sutter-Eyberg Student Behavior Inventory–Revised	Teacher	2-16 y	38

likely to monitor their children's whereabouts; and to be relatively unresponsive to their children's prosocial behavior. Complicating this association is the consistent finding that temperamentally difficult children are more likely to elicit negative parenting responses, including physical punishment, which can exacerbate anger and oppositionality in the child. Other important family-level influences include impaired parent–child attachment, child maltreatment (physical and sexual abuse), exposure to marital conflict and domestic violence, family poverty and crime, and family genetic liability (family histories of the disorders in this class as well as substance use, depressive, bipolar, schizophrenic, somatization, and personality disorders, as well as ADHD, have all been shown to be associated with the development of behavior disorders).

Peer-level influence on the development of behavior problems include peer rejection in childhood and antisocial peer groups, while neighborhood influences include social processes such as collective efficacy and social control.

PREVENTION

A number of studies have assessed the efficacy of programs targeted at the prevention of problem behaviors in children. One of the best researched programs is *Fast Track* (http://fasttrackproject.org), which is a multicomponent school-based intervention comprising a classroom curriculum targeted at conflict resolution and interpersonal skills, parent training, and interventions targeted at the school environment. Implemented in 1st through 10th grade, outcomes at grade 12 demonstrated that intervention decreased the lifetime prevalence of CD, ODD, and ADHD, but only among those at highest initial risk. Another well-researched program, the *Seattle Social Development Project* (http://ssdp-tip.org/SSDP/index.html), also is a multicomponent school-based intervention made up of teacher, parent, and student components targeting classroom management, interpersonal problem-solving skills, child behavior management skills, and academic support skills. Implemented in 1st through 6th grades, outcomes at age 18 yr demonstrated that the intervention decreased school misbehavior and disciplinary actions and violent delinquent acts, as well as demonstrating other favorable academic and behavioral outcomes.

SCREENING/CASE FINDING

The parents of children presenting in the primary care setting should be queried about angry mood or aggressive, defiant, or antisocial behavior as part of the routine clinical interview. A typical screening question would be "Does [name] have a lot of trouble controlling [his/her] anger or behavior?" A number of standardized broad-band screening instruments widely used in the primary care setting *(Pediatric Symptom Checklist*, *Strengths and Difficulties Questionnaire*, *Vanderbilt ADHD Diagnostic Rating Scales)* have items specific to angry mood and/or aggressive behavior, and as such can be used to focus the interview.

Stepped Management

Because of the high rates of response to brief interventions, including bibliotherapy (use of books and other printed material to address emotional or behavioral issues with or without psychotherapy) and other media interventions, clinical practice guidelines increasingly are advocating a stepped approach to the management of youth with behavior problems. The stepped approach involves active case finding and initial management in the primary care setting if appropriate, with referral to increasingly intensive and specialized interventions as indicated by the clinical status of the patient.

Early Intervention

Youth and/or their parents presenting in the primary care setting who self-report or respond affirmatively to queries about difficulties managing angry mood or aggressive or antisocial behavior should be afforded the opportunity to talk about the situation with the pediatric practitioner (in private with the older youth as indicated). By engaging in active listening (e.g., "I hear how you have been feeling. Tell me more about what happened to make you feel that way"), the pediatric practitioner can begin to assess the onset, duration, context, and severity of the symptoms, and associated dangerousness, distress, and functional impairment. In the absence of acute dangerousness (e.g., homicidality, assaultiveness, psychosis, substance abuse) and significant distress or functional impairment, the pediatric practitioner can schedule a follow-up appointment within 1-2 wk to conduct a behavior assessment. At this follow-up visit, to assist with decision making around appropriate level of care, a behavior screening instrument can be administered (Table 29-4) and additional risk factors (see "Etiology/Risk Factors" above) can be explored.

For mild symptoms (manageable by the parent and not functionally impairing) and in the absence of major risk factors (homicidality, assaultiveness, psychosis, substance use, child maltreatment, parental psychopathology, or severe family dysfunction), guided self-help (anticipatory guidance) with watchful waiting may suffice. Guided self-help can include provision of educational materials (pamphlets, books, DVDs, workbooks, Internet sites) that provide information to the youth about dealing with anger-provoking situations, and advice to parents about strengthening the parent–child relationship, effective parenting strategies, and the effects of adverse environmental exposures on the development of behavior problems. An example of a self-help program for parents is the *Positive Parenting Program* (Triple P; www.triplep.net), self-directed version, in which parents are provided with a workbook outlining a 10 wk self-guided program that includes readings and homework tasks. In a Cochrane review, media-based parenting interventions were found to have a moderate, if variable, effect on child behavior problems. If the problematic behavior is occurring predominantly at school, the parent can be advised about the role of a special education evaluation in the assessment and management of the child's misbehavior, including the development of a behavioral intervention plan. During the period of guided self-help, follow-up visits should be scheduled.

If a mental health clinician has been colocated or integrated into the primary care setting, all parents of young children (universal prevention) as well as the parents of youth with behavior problems (indicated prevention) can be provided with a brief version of parent training. For example, *Incredible Years* has a 6-8 session universal prevention version designed for the parents of 2-6 yr old children, and the Triple P program has a universal prevention communications system (print and electronic media) for the parents of youth from birth to the teenage years. For children with behavior problems, the Triple P program has seminar (three 90 min sessions), brief (15-30 min consultations), and primary care (four 20-30 min consultations) versions for the parents

of youth from birth to the teenage years that have been specifically designed for implementation in the primary care setting. These brief interventions focus on strengthening the parent–child relationship, identifying and monitoring the frequency of a problem behavior, and implementing and reviewing the effects of a targeted behavior plan.

Treatment

For youth who continue to have mild to moderate behavior problems after several weeks of guided self-help or a brief course of parent training, or who from the outset exhibit moderate to severe or comorbid aggression, homicidality, assaultiveness, psychosis, or substance use, or who have a history of child maltreatment or severe family dysfunction or psychopathology, assessment (see Chapter 20) and treatment (see Chapter 21) in the specialty mental health setting by a child-trained mental health clinician should be provided. The mental health clinician should be trained to the appropriate level of competence in the specific services the clinician is asked to provide.

The youth's problem behavior may predominantly occur at home, at school, with peers, or in the community, or it may be pervasive. If possible, interventions need to address each context specifically, rather than assuming generalizability of treatment. Thus, for behaviors mostly manifested in the home setting, parent training would be the treatment of choice, whereas for behaviors manifested mostly at school, consultation with the teacher and recommendation of a special education evaluation for service eligibility can be useful. When there are pervasive problems, including aggression toward peers, anger management training can be employed in addition to the other interventions.

Parent training has been extensively studied for the treatment of youth problem behavior. These programs, typically 10-15 wk in duration, focus on some combination of the following components: understanding social learning principles, developing a warm, supportive relationship with the child, encouraging child-directed interaction and play, providing a predictable, structured household environment, setting clear and simple household rules, consistently praising and materially rewarding positive behavior, consistently ignoring annoying behavior (followed by praise when the annoying behavior ceases), and consistently giving consequences (such as time out or loss of privileges) for dangerous or destructive behavior. Other important targets for parenting training include understanding developmentally appropriate moods and behavior, managing difficult temperamental characteristics, fostering the child's social and emotional development, and protecting the child from traumatic exposures. Several of these programs have demonstrated moderate to large effect sizes (0.5-0.8) in multiple randomized trials for short-term reductions in behavior problems. A Cochrane review found group parenting programs to be effective and cost-effective for improving child behavior problems (***standardized mean difference* [SMD]:** –0.53 to –0.72), parental mental health (SMD: –0.36), and parenting skills (SMD: –0.47 to –0.53) among parents of 3-12 yr old children. An earlier Cochrane review concluded that parenting programs can be effective in improving the emotional and behavioral adjustment of 0-3 yr old children.

Parenting programs with effect sizes exceeding 0.20 include *Parent–Child Interaction Therapy*, Triple P, *Helping the Noncompliant Child, Incredible Years,* and *Parent Management Training Oregon.* Parenting programs have been found to be effective in disadvantaged community settings as well as in DVD format (Incredible Years) and over the Internet (Triple P Online), and for some programs effects have been found to be durable over a number of years. Predictors of nonresponse to these interventions have included greater initial symptom severity as well as involvement of the parent with child protection services.

Adherence to the complete treatment regimen has limited the effectiveness of parent training programs. Estimates of premature termination are as high as 50-60%, and termination within 5 treatment sessions is not uncommon. Predictors of premature termination of parent training programs have included single parent status, low family income, low parental education levels, young maternal age, minority group status, and life stresses.

Anger management training programs for misbehaving youth also have been extensively studied. These programs, typically 16-20 weekly sessions in duration, focus on some combination of the following components: emotion awareness, perspective taking, anger management, social problem solving, and goal settings. Among the programs with effect sizes exceeding 0.20 include *Coping Power* and *Problem-Solving Skills Training*.

Multicomponent treatments for serious behavior disorders (such as CD) that target the broader social context include ***Multidimensional Treatment Foster Care*** and ***Multisystemic Therapy***. Multidimensional Treatment Foster Care, delivered in a foster care setting for 6-9 mo, typically includes foster parent training and support; family therapy for biologic parents; youth anger management, social skills, and problem-solving training; school-based behavioral interventions and academic support; and psychiatric consultation and medication management, when needed. Multisystemic Therapy, typically lasting 3-5 mo, generally includes social competence training, parent and family skills training, medications, academic engagement and skills building, school interventions and peer mediation, mentoring and after-school programs, and involvement of child-serving agencies. These multicomponent programs have been designated probably efficacious because of the limited rigorous supporting evidence. Predictors of nonresponse to multicomponent treatments have included higher frequency of rule-breaking behavior and predatory aggression, higher psychopathy scores, and comorbid mood disorders.

Two classes of medication, stimulants and atypical antipsychotics, have strong evidence for the management of impulsive, anger-driven aggressive behavior, although neither are FDA approved for this indication. Resource limitations may necessitate provision of pharmacotherapy in the primary care setting; the safety and efficacy of this practice can be enhanced by regular consultation with a child and adolescent psychiatrist.

In a meta-analysis of pharmacologic treatments for aggression in youth, stimulants had a pooled mean effect size of 0.78. In a systematic review of placebo-controlled efficacy of stimulants for rating-scale assessed aggression, stimulants had a pooled effect size of 0.6 and a ***number needed to treat*** of 4. The doses of stimulants used for aggression are similar to those used for ADHD (average dose for methylphenidate: approximately 1 mg/kg/day).

Stimulants have been well-tolerated by children and adolescents, and all formulations have similar adverse event profiles. The most common (generally dose-dependent) side effects include headache, stomachache, appetite suppression, weight loss, blood pressure and heart rate increases, and delayed sleep onset. Rare side effects include irritability (particularly in younger children) and hallucinations. The cardiac effects of stimulants have been extensively studied, the most recent of which has demonstrated a hazard ratio for serious cardiovascular events of 0.75. Stimulants should be avoided in the presence of structural cardiac abnormalities and patient symptoms (syncope, palpitations, arrhythmias), or family history (e.g., unexplained sudden death) suggestive of cardiovascular disease, without cardiology consultation.

In studies of risperidone in youth with aggressive behavior, the mean effect size for aggression was 0.72. For maintenance treatment, mean effect size was 0.40. The usual daily dose of risperidone for aggression has been suggested to be 1.5-2 mg for children and 2-4 mg for adolescents. The initial starting doses have been suggested to be 0.25 mg for children and 0.5 mg for adolescents, titrating upward to the usual daily dose as indicated and tolerated.

Side effects of antipsychotic medications include sedation, extrapyramidal side effects, withdrawal dyskinesia, hyperprolactinemia, elevated liver transaminases, weight gain, cardiovascular effects, and metabolic abnormalities (elevated glucose and lipids). Ziprasidone is associated with the lowest weight gain followed by aripiprazole, quetiapine, risperidone, and olanzapine. However, ziprasidone has not been recommended for use in children and adolescents due to lack of efficacy data. The excessive weight gain associated with olanzapine precludes its choice as a 1st-line agent.

The side effects of antipsychotic medications warrant close monitoring: abnormal movements should be monitored periodically using a standardized methodology (such as the Abnormal Involuntary

Movement Scale [AIMS] checklist); blood pressure, body mass index and fasting glucose and lipids should be checked at baseline and at regular intervals thereafter, according to standard guidelines. Consideration of weight management interventions and increased monitoring of blood glucose and lipid levels should be implemented if weight gain exceeds 90th percentile body mass index for age, or a change of 5 body mass index units occurs in youths who were obese at the beginning of treatment. In patients with a personal or family history of cardiac abnormalities, including syncope, palpitations, arrhythmias, or sudden unexplained death, a baseline electrocardiogram with subsequent monitoring should be considered, along with cardiology consultation. Alternative pharmacology should be considered if the resting heart rate exceeds 130 beats/min, or the PR, QRS, and QTc exceed 200, 120, and 460 msec, respectively.

Medication trials should be systematic, and the duration of trials should be sufficient (generally 6-8 wk) to determine the agent's effectiveness. The immediate goal of treatment is to achieve at least a 50% reduction in aggressive symptoms as assessed by a standardized rating scale (see Table 29-4). A second medication of the same class can be considered if there is insufficient evidence of response to the maximal tolerated dose by 8 wk. Care should be taken to avoid unnecessary polypharmacy, in part by discontinuing agents that have not demonstrated significant benefit. Discontinuation of the medication should be considered after a symptom-free interval.

LEVEL OF CARE

Most children and adolescents with a behavior disorder can be safely and effectively treated in the outpatient setting. Youths with intractable CD may benefit from residential or specialized foster care treatment, where more intensive treatments can be provided.

Bibliography is available at Expert Consult.

29.1 Age-Specific Behavioral Disturbances

Lovern R. Moseley, Heather J. Walter, and David R. DeMaso

INFANCY AND TODDLERHOOD

Temper tantrums and breath-holding spells are common during the first years of life and are age-typical expressions of frustration or anger. Parents who respond to toddler defiance with punitive anger can reinforce oppositional behavior. Parents are best advised to attempt to avert defiance by giving the child choices; once the child has begun a tantrum, the child can be given a timeout. It is useful to advise parents to tell their child, once he or she is calm, that the reasons for frustration are understandable, but that defiance is not acceptable.

Parents are occasionally concerned about **breath-holding spells.** Although some children hold their breath until they lose consciousness, sometimes leading to a brief seizure, there is no increased risk of seizure disorders in children who have had a seizure during a breath-holding spell. Parents are best advised to ignore breath holding once it has started. Without sufficient reinforcement, breath holding generally disappears.

Subtypes of breath holding spells include cyanotic, pallid, or mixed episodes. Cyanotic are the dominant type and may include a brief loss of consciousness and a very brief tonic-clonic seizure. Pallid spells may be similar to vasovagal related syncopal events in older children and initiated from similar stimuli (see Chapter 69). Iron deficiency with or without anemia may be present and some children with breath-holding spells respond to iron therapy. Medical conditions to consider should include seizures, Chiari crisis, dysautonomia, cardiac arrhythmias, and central nervous system lesions.

The first key to the office management of temper tantrums and breath-holding spells is to help parents to intercede before the child is highly distressed. The pediatrician should advise parents to intercede early in defiant behavior by calmly placing the child in timeout for a period of time approximating 1 min for each year of age. When breath holding does not respond to the parent's coaching or is accompanied by head banging or high levels of aggression, referral for a mental health evaluation is indicated.

If behavioral measures such as timeout fail, pediatricians must assess how the parents handle anger before making further recommendations about how to approach the child. Children can be frightened by the intensity of their own angry feelings and by angry feelings they arouse in their parents. Parents should model the anger control that they wish their children to exhibit. Some parents are unable to see that they lose control themselves; their own angry behavior does not help their children to internalize controls. Advising parents to calmly provide simple choices will help the child to feel more in control and to develop a sense of autonomy. Providing the child with options also typically helps reduce the child's feelings of anger and shame, which can later have adverse effects on social and emotional development.

Lying can be used by 2-4 yr olds as a method of playing with the language. By observing the reactions of parents, preschoolers learn about expectations for honesty in communication. Lying can also be a form of fantasy for children, who describe things as they wish them to be rather than as they are. To avoid an unpleasant confrontation, a child who has not done something that a parent wanted may say that it has been done. The child's sense of time and reason does not permit the realization that this only postpones a confrontation.

CHILDHOOD AND ADOLESCENCE

Lying

In **school-age children,** lying is generally an effort to cover up something that the child does not want to accept in his or her own behavior. The lie is invented to achieve a temporary good feeling and to protect the child against a loss of self-esteem. Habitual lying also can be promoted by poor adult modeling. Many adolescents lie to avoid adults' disapproval; lying may be used as a method of rebellion. Chronic lying can occur in combination with several other antisocial behaviors and is a sign of underlying psychopathology or family dysfunction.

Regardless of age or developmental level, when lying becomes a common way of managing conflict, intervention is warranted. Initially, the parents should confront the child to give a clear message of what is acceptable. Sensitivity and support combined with limit-setting are necessary for a successful intervention. If this behavior cannot be resolved through the parents' understanding of the situation and the child's understanding that lying is not a reasonable alternative, a mental health evaluation is indicated.

Stealing

Many children **steal** something at some point in their lives. When preschoolers and school-age children steal more than once or twice, the behavior may be a response to stressful environmental circumstances. Stealing can be an expression of anger or revenge for perceived frustrations with parents. In some instances, stealing becomes 1 way the child or adolescent can manipulate and attempt to control the child's or adolescent's world. Stealing also can be learned from adults.

It is important for parents to help the child undo the theft by returning the stolen articles or by rendering their equivalent either in money that the child can earn or in services. When stealing is part of a pattern of conduct problems, referral for a mental health evaluation is warranted.

Truancy and Running Away

Truancy and running away are never developmentally appropriate. Truancy may represent disorganization within the home, caretaking needs of younger siblings, developing conduct problems, or emotional problems including depression or anxiety. Whereas younger children may threaten to run away out of frustration or a desire to get back at parents, older children who run away are almost always expressing a serious underlying problem within themselves or their family, including violence, abuse, and neglect. Adolescent runaways are at high risk for substance abuse, unsafe sexual activity, and other risk-taking behaviors. Youth exhibiting truancy or running away should be referred for a mental health evaluation.

Fire Setting

Although interest in fire is common in early childhood, unsupervised **fire setting** is always inappropriate because of its extreme dangerousness. School-age children may set fires accidentally, or because of curiosity or latent hostility. These young children usually set fires by themselves within their homes. In adolescence, fire setting can be a sign of delinquency or a signal of traumatic experiences. Fire setting always requires intervention by a mental health clinician. A thorough mental health evaluation is necessary to plan the components of a successful treatment program.

Aggression and Bullying

See also Chapter 39.1.

Aggression and bullying are serious symptoms and are associated with significant morbidity and mortality. Children might not grow out of this behavior; early intervention is indicated for persistent aggressive behavior. Aggressive tendencies are heritable, although environmental factors can promote aggression in susceptible children. Both enduring and temporary stressors affecting a family can increase aggressive behavior in children. Aggression in childhood is correlated with a chaotic and impoverished family home that could be the result of chronic unemployment, family discord, exposure to community and domestic violence, criminality and psychiatric disorders as well as births to teenage mothers and those with limited resources and support. Boys are almost universally reported to be more aggressive than girls. A difficult temperament and later aggressiveness are related, although there is evidence that these children elicit punitive caregiving within the family environment, setting up a cycle of increasing aggression. Aggressive children often misperceive social cues and react with inappropriate hostility toward peers and parents.

Clinically, it is important to differentiate the causes and motives for childhood aggression. Intentional aggression may be primarily instrumental, to achieve an end, primarily hostile, to inflict physical or psychologic pain, or primarily angry and impulsive. Children who are callous and not empathetic and who are often aggressive require mental health intervention. These children are at high risk for suspension from school and eventual school failure. Learning disorders are common, and aggressive children should be screened. Other forms of psychopathology may be present; in particular, aggressive children might have ADHD, ODD, IED, CD, and/or disruptive mood dysregulation disorder.

Aggressive behavior in boys is relatively consistent from the preschool period through adolescence; a boy with a high level of aggressive behavior at 3-6 yr of age has a high probability of carrying this behavior into adolescence, especially without effective intervention. The developmental progression of aggression among girls is less-well studied. There are fewer girls with physically aggressive behavior in early childhood; interpersonal coercive behavior, especially in peer relationships, is not uncommon among girls and may be related to the development of more physical aggression in adolescence (fighting, stealing).

Children exposed to aggressive models on television, in video games, or in play show more aggressive behavior compared with children not exposed to these models. Parents' anger and aggressive or harsh punishment model behavior that children might imitate when they are physically or psychologically hurt. Parents' abuse may be transmitted to the next generation by several modes: children imitate aggression that they have witnessed, abuse can cause brain injury (which itself predisposes the child to violence), and internalized rage often results from abuse.

Cutting and Other Self-Injurious Behaviors

Cutting and other self-injurious behaviors have been occurring in increased rates among children as young as age 11 yr through adolescence. Rates are higher in girls than boys, but cutting and other self-injurious behaviors do occur in both. The behavior involves the deliberate carving, cutting, scratching, or burning of the skin with fingernails or other objects sharp enough to cause injury (razors, scissors, broken glass, hard plastic, knives, staples, fire). Oftentimes the behavior does not occur with the intention of suicide but can be associated with it and can unintentionally result in significant harm or even death. Youth often report that they have friends who "cut" and have reported that it is a way to feel better and so they have tried it as well. There is increased access to message boards and websites on the internet where youth have shared their stories of self-injury; these postings may have contributed to experimentation. The behavior is usually triggered by psychological distress and is also correlated with depression, anxiety, peer victimization, low self-esteem, substance abuse, eating disorders, impulsivity, delinquency, and neglectful or highly punitive parenting practices, as well as a history of physical or sexual abuse. Parents should be advised to monitor their children's media access and be aware of their peer group. Learning that their child has been engaging in this behavior can be very frightening for parents as they are unsure of what to do or the reasons why their child is engaging in this behavior. It is imperative that they seek mental healthcare for their child.

Chapter 30

Autism Spectrum Disorder

Giuseppe J. Raviola, Michael L. Trieu, David R. DeMaso, and Heather J. Walter

The essential features of ***autism spectrum disorder* (ASD)** are persistent impairment in reciprocal social communication and interaction, and restricted, repetitive patterns of behavior or interests (Table 30-1). ASD encompasses disorders previously referred to as early infantile autism, childhood autism, Kanner autism, high functioning autism, atypical autism, Asperger disorder, childhood disintegrative disorder, and pervasive developmental disorder not otherwise specified. These specific diagnoses are not reliably distinguishable or consistently applied across different treatment centers. Individuals diagnosed with one of these previous diagnoses should be given the diagnosis of ASD.

DESCRIPTION

Social Communication and Interaction Deficits

Aberrant development of social communication and impaired ability to engage in reciprocal social interactions are hallmark symptoms of ASD. Deficits in social–emotional reciprocity (the ability to engage with others and share thoughts and feelings) are evident early in children with ASD who show little or no initiation of social interaction and little or no sharing of emotions or imitative behaviors. Children may present with abnormal social approach, failure of back-and-forth conversation, and difficulties processing and responding to complex social cues. Infants <6 mo of age may or may not demonstrate features typical of ASD.

Impairments in nonverbal social communication are manifested by absent, reduced, or atypical use of eye contact, gestures, facial expressions, body orientation, or speech intonation. Youth may fail to smile, orient to name, or use gestures to point or show. Abnormal eye contact with failure to follow someone's pointing or eye gaze is characteristic. In patients with fluent language, poorly integrated verbal and nonverbal communication may result in odd, wooden, or exaggerated body language during social interactions (Table 30-2).

Children with ASD may demonstrate absent, reduced, or atypical social interest, manifested by rejection of others, passivity, or inappropriate approaches that seem aggressive and disruptive. In young children, lack of shared, age-appropriate flexible pretend and symbolic play is seen, with children often insistent on playing by very fixed rules.

Table 30-1 DSM-5 Diagnostic Criteria for Autism Spectrum Disorder

A. Persistent deficits in social communication and social interaction across multiple contexts, as manifested by the following, currently or by history:
   1. Deficits in social-emotional reciprocity.
   2. Deficits in nonverbal communicative behaviors used for social interaction.
   3. Deficits in developing, maintaining, and understanding relationships.

B. Restricted, repetitive patterns of behavior, interests, or activities, as manifested by at least two of the following, currently or by history:
   1. Stereotyped or repetitive motor movements, use of objects, or speech.
   2. Insistence on sameness, inflexible adherence to routines, or ritualized patterns of verbal or nonverbal behavior.
   3. Highly restricted, fixated interests that are abnormal in intensity or focus.
   4. Hyper- or hyporeactivity to sensory input or unusual interest in sensory aspects of the environment.

C. Symptoms must be present in the early developmental period (may not become fully manifest until social demands exceed limited capacities, or may be masked by learned strategies in later life).

D. Symptoms cause clinically significant impairment in social, occupational, or other important areas of current functioning.

E. These disturbances are not better explained by intellectual disability (intellectual developmental disorder) or global developmental delay.

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, pp. 50–51.

Children with ASD may prefer solitary activities and interactions with much younger or older people. A desire to establish friendships without complete understanding of the components of friendship (one-sided friendships based solely on shared special interests) can be seen in some children, while an absence of interest in peers may be seen in others. Some youth show deficits in empathy and understanding what another person might be thinking.

Restricted and Repetitive Patterns

The second core characteristic of ASD is restricted, repetitive patterns of behavior, interests, or activities. These include stereotyped movements (hand flapping, finger flicking), repetitive use of objects (spinning coins, lining up toys), repetitive and abnormal speech (echolalia [delayed or immediate parroting of heard words], pronoun reversal, nonsense rhyming, idiosyncratic phrases); insistence on sameness and inflexible adherence to routines or ritualized patterns of behavior (distress at small changes, insistence on adherence to rules, rituals and routines, rigid thinking, repetitive questioning); highly restricted and fixed interests of abnormal intensity or focus (e.g., strong attachment to or preoccupation with unusual objects, excessively circumscribed or perseverative interests); and hyper- or hyporeactivity to sensory input or unusual interest in sensory aspects of the environment (e.g., extreme responses to specific sounds or textures, excessive smelling or touching of objects, fascination with lights or spinning objects, apparent indifference to pain, heat, or cold) (see Table 30-2).

The symptoms of ASD must be present in the early developmental period, must cause clinically significant functional impairment, and must not be better explained by intellectual disability or global developmental delay.

Severity

The severity of ASD is based on evaluations of impairment caused by both deficits in social communication and in restricted, repetitive behaviors. Within these 2 categories, severity is rated levels 1-3, with level 3 implying most severe deficit with a need for the most substantial support (Table 30-3).

Specifiers/Associated Features

ASD is specified as occurring with or without accompanying intellectual and language impairment, and associated with a known medical or genetic condition, environmental factor, or other neurodevelopmental, mental, or behavioral disorder. Children with ASD vary in their verbal abilities. Language level in individuals with ASD "without accompanying language impairment" may speak in full sentences or have fluent speech. ASD specified "with accompanying language impairment" can range from nonverbal speech to single word or phrase speech (capable of imitating songs, rhymes, or television commercials). Receptive language may lag behind expressive language development in ASD. Early abnormal language concerns include absent babbling or gestures by 12 mo, absent single words by 16 mo, and absent 2-word purposeful phrases by 24 mo, as well as any loss of language or social skills at any time. Language, if present, is often one-sided, lacking social reciprocity, idiosyncratic, repetitive, and used to request or label rather than comment, share feelings, or converse.

Intellectual functioning can vary from intellectual impairment (intellectual developmental disorder) to superior intellectual functioning in select areas (splinter skills, savant behavior) ("with or without accompanying intellectual impairment"). Some children show typical development in certain skills and can even show areas of strength in specific areas (puzzles, art, or music). The intellectual profile of an individual may be uneven, with gaps in verbal and nonverbal learning ability and intellectual and adaptive functional skills.

Motor deficits, including odd gait, clumsiness, dyspraxia, and other abnormal motor signs (e.g., walking on tiptoes) are often present. Stereotypic movement or tic disorders may go unnoticed given aforementioned restricted behavioral patterns. Self-injury (head banging, biting the wrist) may occur. Some youth develop catatonic-like motor behavior (slowing and "freezing" mid-action) though most do not go onto develop a full episode with mutism, posturing, grimacing, and waxy flexibility.

Epilepsy is a common comorbidity, and any type of seizure may be observed in ASD. Epilepsy is associated with greater intellectual disability and lower verbal ability. Mutations in the *BCKD-kinase* gene is a syndrome associated with autism, epilepsy and intellectual disability. Youth with ASD are also prone to anxiety and depression as well as abnormalities in attention and hyperactivity.

Language, social, or a mixed pattern of regression may occur in the first 1-2 years. In some, a diagnosis of Landau Kleffner syndrome is identified; in others regression may be due to the onset of epilepsy or abnormal EEG findings in the absence of clinical seizures. Levetiracetam also causes a reversible autistic regression syndrome.

EPIDEMIOLOGY

The Centers for Disease Control and Prevention estimates the prevalence of ASD in the United States as 11.3/1,000 (prior estimated prevalence range: 0.7/10,000 to 72.6/10,000 across 36 earlier surveys). Recent higher reported rates of the disorder appear to be related to differences in diagnostic criteria and practices, inclusion of subthreshold cases, age of children screened, and location of the study. The male : female ratio is estimated to be 4 : 1. The incidence of ASD may be higher in immigrant populations.

ETIOLOGY/RISK FACTORS

Genetic and Familial Factors

There is a high recurrence risk (2-19%) for ASD among siblings, as well as a higher concordance rate (37-90%) in twin studies. Closer spacing of pregnancies, advanced maternal or paternal age, and extremely premature birth (<26 wk gestational age) as well as family members with learning problems, psychiatric disorders, and social disability, have been identified as risk factors. Multiple genes are viewed as involved in autism with studies supporting a role for both common (>5% of general population) and rare genetic variations contributing to the disorder. For example, Timothy syndrome, characterized by

Table 30-2 Signs and Symptoms of Possible Autism in Preschool Children (or Equivalent Mental Age)

Social interaction and reciprocal communication behaviors

Spoken language
- Language delay (in babble or words—for example, using fewer than 10 words by the age of 2 yr)
- Regression in or loss of use of speech
- Spoken language (if present) may include unusual features, such as: vocalizations that are not speech-like; odd or flat intonation; frequent repetition of set words and phrases (echolalia); reference to self by name or "you" or "she" or "he" beyond age 3 yr
- Reduced and/or infrequent use of language for communication—for example, use of single words, although able to speak in sentences

Responding to others
- Absent or delayed response to name being called, despite normal hearing
- Reduced or absent responsive social smiling
- Reduced or absent responsiveness to other people's facial expressions or feelings
- Unusually negative response to the requests of others ("demand avoidance" behavior)
- Rejection of cuddles initiated by parent or carer, although the child himself or herself may initiate cuddles

Interacting with others
- Reduced or absent awareness of personal space, or unusually intolerant of people entering their personal space
- Reduced or absent social interest in others, including children of his or her own age—may reject others; if interested in others, he or she may approach others inappropriately, seeming to be aggressive or disruptive
- Reduced or absent imitation of others' actions
- Reduced or absent initiation of social play with others, plays alone
- Reduced or absent enjoyment of situations that most children like—for example, birthday parties
- Reduced or absent sharing of enjoyment

Eye contact, pointing, and other gestures
- Reduced or absent use of gestures and facial expressions to communicate (although may place an adult's hand on objects)
- Reduced and poorly integrated gestures, facial expressions, body orientation, eye contact (looking at people's eyes when speaking), and speech used in social communication
- Reduced or absent social use of eye contact (assuming adequate vision)
- Reduced or absent "joint attention" (when 1 person alerts another to something by means of gazing, finger pointing, or other verbal or nonverbal indication for the purpose of sharing interest). This would be evident in the child from lack of:
  - Gaze switching
  - Following a point (looking where the other person points to—may look at hand)
  - Using pointing at or showing objects to share interest

Ideas and imagination
- Reduced or absent imagination and variety of pretend play

Unusual or restricted interests and/or rigid and repetitive behaviors
- Repetitive "stereotypical" movements such as hand flapping; body rocking while standing; spinning; finger flicking
- Repetitive or stereotyped play—for example, opening and closing doors
- Over focused or unusual interests
- Excessive insistence on following own agenda
- Extremes of emotional reactivity to change or new situations; insistence on things being "the same"
- Over-reaction or under-reaction to sensory stimuli, such as textures, sounds, smells
- Excessive reaction to the taste, smell, texture, or appearance of food, or having extreme food fads

From Baird G, Douglas HR, Murphy MS: Recognizing and diagnosing autism in children and young people: summary of NICE guidance. BMJ 343:d6360, 2011, Box 1, p. 901.

Table 30-3 DSM-5 Severity Levels for Autism Spectrum Disorder

SEVERITY LEVEL	SOCIAL COMMUNICATION	RESTRICTED, REPETITIVE BEHAVIORS
Level 3 "Requiring very substantial support"	Severe deficits in verbal and nonverbal social communication skills cause severe impairments in functioning, very limited initiation of social interactions, and minimal response to social overtures from others. *For example,* a person with few words of intelligible speech who rarely initiates interaction and, when he or she does, makes unusual approaches to meet needs only and responds to only very direct social approaches	Inflexibility of behavior, extreme difficulty coping with change, or other restricted/repetitive behaviors markedly interfere with functioning in all spheres. Great distress/difficulty changing focus or action.
Level 2 "Requiring substantial support"	Marked deficits in verbal and nonverbal social communication skills; social impairments apparent even with supports in place; limited initiation of social interactions; and reduced or abnormal responses to social overtures from others. *For example,* a person who speaks simple sentences, whose interaction is limited to narrow special interests, and who has markedly odd nonverbal communication	Inflexibility of behavior, difficulty coping with change, or other restricted/repetitive behaviors appear frequently enough to be obvious to the casual observer and interfere with functioning in a variety of contexts. Distress and/or difficulty changing focus or action.
Level 1 "Requiring support"	Without supports in place, deficits in social communication cause noticeable impairments. Difficulty initiating social interactions, and clear examples of atypical or unsuccessful responses to social overtures of others. May appear to have decreased interest in social interactions. *For example,* a person who is able to speak in full sentences and engages in communication but whose to-and-fro conversation with others fails, and whose attempts to make friends are odd and typically unsuccessful	Inflexibility of behavior causes significant interference with functioning in one or more contexts. Difficulty switching between activities. Problems of organization and planning hamper independence.

From the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, p. 52.

dysmorphic facies, congenital heart disease, prolonged QT interval, and developmental delay, is caused by a mutation in the L-type calcium channel $Ca_v1.2$ and also has ASD features. In addition, ASD is associated with multiple abnormalities of mitochondrial DNA.

Neurobiologic Factors

The high rates of seizure disorder suggest a role for neurobiologic factors in ASD. The number of different areas of the brain affected by autism suggests a diverse and widely distributed set of affected neural systems. Postmortem studies reveal various abnormalities, particularly within the limbic system. Structural MRI reveals an overall increase of brain size, and diffusion tensor imaging studies suggest aberrations in white matter tract development. Functional MRI identifies difficulties in tasks involving social and affective judgments and differences in the processing of face and nonface stimuli. Poor neuronal connectivity in various brain regions also is reported. Elevated peripheral levels of serotonin are a replicated neurochemical finding of unclear significance. A role for dopamine is suggested given the problems with overactivity and stereotyped mannerisms and the positive response of such behaviors to antipsychotic medications.

Neuropsychological correlates of ASD include impairments in executive functioning (e.g., simultaneously engaging in multiple tasks), weak central coherence (integrating information into meaningful wholes), and deficits in theory of mind tasks (taking the perspective of another person). The empathizing-systemizing personality theory describes the autistic mind in terms of impaired empathy alongside intact or even superior systemizing (the drive to analyze or construct systems).

Environmental exposures early in the 1st trimester of pregnancy that have been linked to ASD in epidemiologic studies include thalidomide, misoprostol, rubella infection, valproic acid, and the organophosphate insecticide chlorpyrifos. Prenatal folic acid supplementation may reduce the risk of ASD. There has been concern about vaccines as a postnatal environmental cause for ASD. The focus has been on either the measles-mumps-rubella vaccine or the thimerosal preservative as a causative factor. All available data have not supported either hypothesis.

Neuropathology Factors

The head circumference in ASD is normal or slightly smaller than normal at birth until 2 mo of age. Afterward, children with ASD show an abnormally rapid increase in head circumference from 6-14 mo of age, increased brain volume in 2-4 yr olds, increased volume of the cerebellum, cerebrum, and amygdala, and marked abnormal growth in the frontal, temporal, cerebellar, and limbic regions of the brain. Early, accelerated brain growth during the first several years of life is followed by abnormally slow or arrested growth, resulting in areas of underdeveloped and abnormal circuitry in parts of the brain. Areas of the brain responsible for higher-order cognitive, language, emotional, and social functions are most affected.

CLINICAL COURSE

ASD symptoms are typically recognized during the 2nd yr of life but can been seen earlier than 12 mo if developmental delays are severe. Initial symptoms most frequently involve delayed language accompanied by lack of social interest or odd play patterns. During the 2nd yr, odd and repetitive behaviors and the absence of typical play become more apparent. It is typical for parents to report that there was no period of normal development or that there was a history of unusual behaviors. Less commonly (in 20-40% of cases), a period of apparently normal development is reported before a loss of skills. In adolescence, a small number of individuals with ASD make marked developmental gains; another subgroup will deteriorate (self-injury, aggression).

DIFFERENTIAL DIAGNOSIS

ASD must be differentiated from communication disorders (especially social communication disorder), intellectual disability (see Chapter 36), sensory impairments (especially deafness), reactive attachment disorder, obsessive-compulsive and related disorders, anxiety disorders (see Chapter 25) including selective mutism, schizophrenia (see Chapter 31), stereotypic movement disorder (see Chapter 24.2), attention-deficit/hyperactivity disorder (ADHD), and Rett syndrome (see Chapter 599).

Autistic-like behavior has been noted in many metabolic syndromic and genetic disorders. These include adenylosuccinate lyase deficiency, PKU, glucose-6-phosphatase deficiency, adenosine deaminase deficiency, succinic semialdehyde dehydrogenase deficiency, disorders of creatine transport and metabolism, propionic acidemia, MELAS and other mitochondrial disorders, Danan disease, tuberous sclerosia, fragile X syndrome, Smith Lemli Opitz syndrome, myotonic dystrophy, dystrophinopathies, Cohen and Myhre syndromes, muscle-eye-brain disease, and various genetic microdeletions or duplications, including deletion 22q11.2.

Developmental language disorders and intellectual disability have an impact on socialization and may be mistaken for ASD. The distinction is particularly difficult in preschool children. When an individual shows impairment in social communication and social interactions but without abnormal nonverbal communication or restricted, repetitive patterns of behavior, a diagnosis of *social communication disorder* should be considered. If there is no apparent discrepancy between the level of social-communicative skills and other intellectual skills, a diagnosis of intellectual disability should be considered.

Children with reactive attachment disorder (typically occurring in the face of emotional neglect; see Chapter 40) may exhibit deficits in attachment and therefore inappropriate social responsivity, but these usually improve substantially if adequate caretaking is provided. Obsessive-compulsive disorder (see Chapter 25) has a later onset than ASD, is not typically associated with social and communicative impairments, and is characterized by repetitive patterns of behavior that are ego dystonic. Symptoms that characterize anxiety disorders, such as excessive worry, the need for reassurance, the inability to relax, and feelings of self-consciousness are also seen in ASD, particularly among higher functioning individuals. However, the 2 conditions can be differentiated by the prominent social and communicative impairments seen in ASD but not anxiety disorders, and the developed social insight of children with anxiety disorders, which is not seen in ASD. Differentiating childhood schizophrenia from autism can be difficult, as both are characterized by social impairments and odd patterns of thinking; florid delusions and hallucinations are rarely seen in autism.

Motor stereotypies are among the diagnostic criteria for ASD, so an additional diagnosis of stereotypic movement disorder should not be given if the movements are better explained by ASD. However when stereotypies cause self-injury and become a focus of treatment, both diagnoses may be appropriate. Similarly, an additional diagnosis of ADHD should only be given when attentional difficulties or hyperactivity exceed those typically observed in children of comparable mental age.

During the regressive phase of Rett syndrome (ages 1-4 yr), disruptive social interaction may be observed and affected children may meet diagnostic criteria for ASD. After this phase, social communication improves and an additional diagnosis of ASD should be considered only if all criteria for ASD are met.

COMORBIDITIES

Given difficulties in communication (mutism) and cognitive impairment, issues of comorbidity in ASD can be quite complex. The process of diagnostic overshadowing (the tendency to fail to diagnosis other comorbid conditions when a more noticeable condition is present) may occur. Most studies do show increased rates of anxiety and attentional disorders.

In most epidemiologically based samples of persons with autistic disorder, approximately 50% exhibit severe or profound intellectual disability, 35% exhibit mild to moderate intellectual disability, and the remaining 20% have IQs in the normal range. Verbal skills are typically more impaired than nonverbal skills. Intellectual impairment is not an essential diagnostic feature of autism; it is necessary and important for the diagnosis of intellectual disability to be made.

Neurologic comorbidities include epilepsy, sleep dysfunction, motor delay, dyspraxia, incoordination, and gait disturbances.

A range of behavioral difficulties can be observed in ASD including hyperactivity, obsessive compulsive phenomena, self-injury, aggression, stereotypies, tics, and affective symptoms. The issue of whether these qualify as additional disorders is complex. Affective symptoms are frequently observed and include lability, inappropriate affective responses, anxiety, and depression. Impairments in emotion regulation processes can lead to under- and overreactivity. Overt clinical depression is sometimes observed, and this may be particularly true for adolescents. Case reports and case series suggest possible associations with bipolar disorders and tic disorders. Attentional difficulties (ADHD) are also frequent in autism, reflecting cognitive, language, and social problems.

SEQUELAE

Most persons with ASD remain within the spectrum as adults, and regardless of their intellectual functioning, continue to experience problems with independent living, employment, social relationships, and mental health. Some children, especially those with communication abilities, can grow up to live self-sufficient lives in the community with employment. Others remain dependent on their family or require placement in facilities outside the home. Because early, intensive therapy can improve language and social function, delayed diagnosis can lead to a poorer outcome. A better prognosis is associated with higher intelligence, functional speech, and less-bizarre symptoms and behavior. The symptom profile for some children might change as they grow older, and risk of seizures or self-injurious behavior becomes more common. ASD is not a degenerative disorder and it is typical for learning and compensation to continue throughout life.

SCREENING/CASE FINDING

All children should receive autism-specific screening at 18 and 24 mo of age, in addition to broad developmental screening at 9, 18, and 24 mo (Fig. 30-1). In some instances screening may be relevant to older children, such as those who are more intellectually able and whose

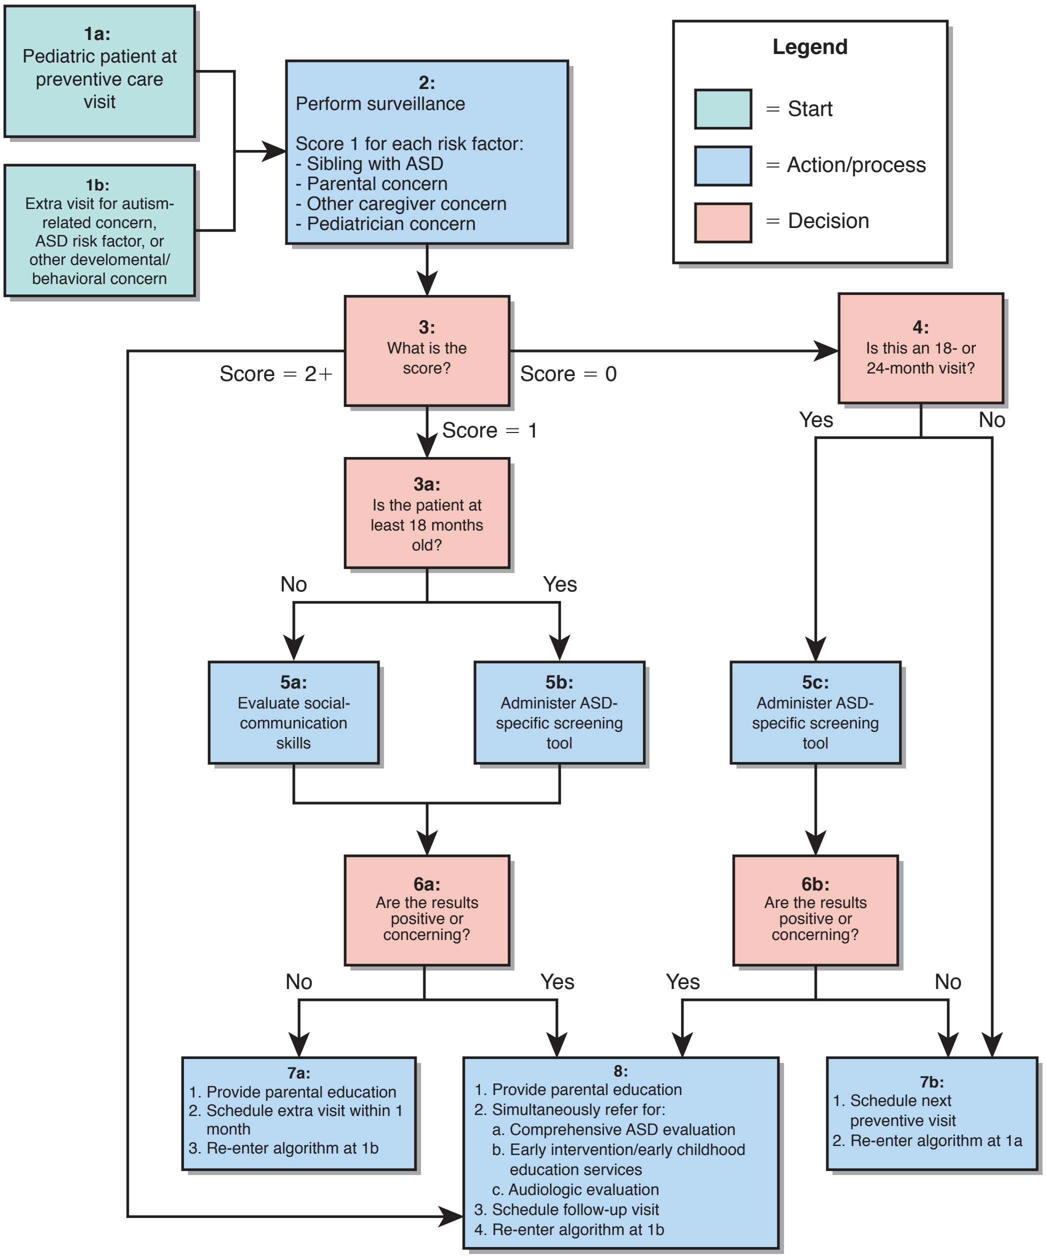

Figure 30-1 Surveillance and screening algorithm: autism spectrum disorders (ASDs). *(From Plauche Johnson C, Myers SM, Council on Children with Disabilities: Identification and evaluation of children with autism spectrum disorders, Pediatrics 120:1183–1215, 2007.)*

1a:
Pediatric patient at preventive care visit

1a - Developmental concerns, including those about social skill deficits should be included as one of several health topics addressed at each pediatric preventive care visit through the first 5 years of life. *(Go to step 2)*

1b:
Extra visit for autism-related concern, asd risk factor, or other developmental/behavioral concern

1b - At the parents' request, or when a concern is identified in a previous visit, a child may be scheduled for a "problem-targeted" clinic visit because of concerns about ASD. Parent concerns may be based on observed behaviors, social or language deficits, issues raised by other caregivers, or heightened anxiety produced by ASD coverage in the media. *(Go to step 2)*

2:
Perform surveillance

Score 1 for each risk factor:
- Sibling with ASD
- Parental concern
- Other caregiver concern
- Pediatrician concern

2 - Developmental surveillance is a flexible, longitudinal, continuous, and cumulative process whereby health care professionals identify children who may have developmental problems. There are 5 components of developmental surveillance: eliciting and attending to the parents' concerns about their child's development, documenting and maintaining a developmental history, making accurate observations of the child, identifying the risk and protective factors, and maintaining an accurate record and documenting the process and findings. The concerns of parents, other caregivers, and pediatricians all should be included in determining whether surveillance suggests that the child may be at risk of an ASD. In addition, younger siblings of children with an ASD should also be considered at risk, because they are 10 times more likely to develop symptoms of an ASD than children without a sibling with an ASD. Scoring risk factors will help determine the next steps, *(Go to step 3)*

For more information on developmental surveillance, see "Identifying Infants and Young Children With Developmental Disorders in the Medical Home: An Algorithm for Developmental Surveillance and Screening" (Pediatrics 2006; 118:405-420).

3:
What is the score?

3 - Scoring risk factors:

- If the child does not have a sibling with an ASD and there are no concerns from the parents, other caregivers, or pediatrician: Score = 0 *(Go to step 4)*
- If the child has only 1 risk factor, either a sibling with ASD or the concern of a parent, caregiver, or pediatrician: Score = 1 *(Go to step 3a)*
- If the child has 2 or more risk factors: Score = 2+ *(Go to step 8)*

3a:
Is the patient at least 18 months old?

3a -

- If the child's age is $<$18 months, *(Go to step 5a)*
- If the child's age is ≥18 months, *(Go to step 5b)*

4:
Is this an 18-or 24-month visit?

4 - In the absence of established risk factors and parental/provider concerns (score = 0), a level-1 ASD-specific tool should be administered at the 18- and 24-month visits. *(Go to step 5c)* If this is not an 18- or 24-month visit, *(Go to step 7b)*.

Note: In the AAP policy, "Identifying Infants and Young Children With Developmental Disorders in the Medical Home: An Algorithm for Developmental Surveillance and Screening", a general developmental screen is recommended at the 9-, 18-, and 24-or 30-month visits and an ASD screening is recommended at the 18-month visit. This clinical report also recommends an ASD screening at the 24-month visit to identify children who may regress after 18 months of age.

5a:
Evaluate social-communication skills

5a - If the child's age is $<$18 months, the pediatrician should use a tool that specifically addresses the clinical characteristics of ASDs, such as those that target social-communication skills. *(Go to step 6a)*

5b:
Administer ASD-specific screening tool

5b - If the child's age is ≥18 months, the pediatrician should use an ASD-specific screening tool. *(Go to step 6a)*

5c:
Administer ASD-specific screening tool

5c - For all children ages 18 or 24 months, (regardless of risk factors), the pediatrician should use an ASD-specific screening tool. *(Go to step 6b)*

AAP-recommended strategies for using ASD screening tools: "Autism: Caring for Children with Autism Spectrum Disorders: A Resource Toolkit for Clinicians" (in press)*

6a:
Are the results positive or concerning?

6a - When the result of the screening is *negative*, *Go to step 7a*

When the result of the screening is *positive*, *Go to step 8*

6b:
Are the results positive or concerning?

6b - When the result of the ASD screening (at 18- and 24-month visits) is *negative*, *Go to step 7b*

When the result of the ASD screening (at 18- and 24-month visits) is *positive*, *Go to step 8*

7a:
1. Provide parental education
2. Schedule extra visit within 1 month
3. Re-enter algorithm at 1b

7a - If the child demonstrates risk but has a negative screening result, information about ASDs should be provided to parents. The pediatrician should schedule an extra visit within 1 month to address any residual ASD concerns or additional developmental/behavioral concerns after a negative screening result. The child will then re-enter the algorithm at 1b. A "wait-and-see" approach is discouraged. If the only risk factor is a sibling with an ASD, the pediatrician should maintain a higher index of suspicion and address ASD symptoms at each preventive care visit, but an early follow-up within 1 month is not necessary unless a parental concern subsequently arises.

7b:
1. Schedule next preventive visit
2. Re-enter algorithm at 1a

7b - If this is not an 18- or 24-month visit, or when the result of the ASD screening is *negative*, the pediatrician can inform the parents and schedule the next routine preventive visit. The child will then re-enter the algorithm at 1a.

8:
1. Provide parental education
2. Simultaneously refer for:
   a. Comprehensive ASD evaluation
   b. Early intervention/early childhood education services
   c. Audiologic evaluation
3. Schedule follow-up visit
4. Re-enter algorithm at 1b

8 - If the screening result is *positive* for possible ASD in step 6a or 6b, the pediatrician should provide peer reviewed and/or consensus-developed ASD materials. Because a positive screening result does not determine a diagnosis of ASD, the child should be referred for a comprehensive ASD evaluation, to early intervention/early childhood education services (depending on child's age), and an audiologic evaluation. A categorical diagnosis is not needed to access intervention services. These programs often provide evaluations and other services even before a medical evaluation is complete. A referral to intervention services or school also is indicated when other developmental/behavioral concerns exist, even though the ASD screening result is negative. The child should be scheduled for a follow-up visit and will then re-enter the algorithm at 1b. All communication between the referral sources and the pediatrician should be coordinated.

AAP information for parents about ASDs includes: "*Is Your One-Year-Old Communicating with You?*" and "*Understanding Autism Spectrum Disorders.*"

*Available at www.aap.org

Figure 30-1, cont'd

social disability is therefore more likely to be detected later. A number of screening instruments for ASD have been developed that may be helpful to the pediatric practitioner. For example, the Modified Checklist for Autism in Toddlers (M-CHAT) is a free online 23-item autism screening tool designed to identify children 16-30 mo of age who should receive a more thorough assessment for possible early signs of ASD or developmental delay (https://www.m-chat.org/index.php).

ASSESSMENT

If screening indicates ASD symptomatology, a thorough diagnostic assessment should be performed to determine whether full criteria are met. Multidisciplinary assessment is optimal in facilitating early diagnosis, treatment, and coordinated multiagency collaboration. Evaluations from various professionals, including a developmental pediatrician or pediatric neurologist, medical geneticist, child and adolescent psychiatrist, speech-language pathologist, occupational or physical therapist, or medical social worker may be indicated. The *Autism Diagnostic Observation Schedule* (ADOS), which is a semistructured interactive examination by a professional trained in its administration, is the standard diagnostic tool. *The use of such instruments supplements, but does not replace, informed clinical judgment*.

All children with ASD should have a medical assessment, which typically includes a physical examination, a hearing screen, a Wood's lamp examination for signs of tuberous sclerosis (see Chapter 596.2), and genetic testing, which should include ***chromosomal microarray* (CMA)**. In a community sample of children with ASD, diagnostic yield 0.57% for fragile X testing, and 24% for CMA. CMA is recommended by medical geneticists as the standard of care for the initial evaluation of children with ASD, but does not always detect fragile X or Rett syndromes.

Unusual features in the child (dysmorphology, staring spells) should prompt additional evaluations. The categories of potential organic etiologies includes infectious (encephalitis or meningitis), endocrinologic (hypothyroidism), metabolic (homocystinuria, phenylketonuria), traumatic (head injury), toxic (fetal alcohol syndrome), or genetic (chromosomal abnormality). Certain developmental disorders, most notably Landau-Kleffner syndrome, should be ruled out (characterized by a highly distinctive electroencephalogram abnormality and marked aphasia). Neuroimaging, electroencephalography, and additional laboratory tests should be obtained when relevant, based on examination or history (testing for the *MeCP2* gene in females for possible Rett disorder). Table 30-4 summarizes potential medical tests in the assessment of ASD.

Psychological assessments that clarify cognitive ability and adaptive skills are indicated for treatment planning. Deficits in language and socialization often make it difficult to obtain an accurate estimate of a child's intellectual potential. Some children with ASD perform adequately on nonverbal tests, and those with developed speech can show adequate intellectual capacity. Communication assessment, including measures of both receptive and expressive vocabulary as well as language use (particularly social or pragmatic), is also helpful relative to diagnosis and treatment planning. Occupational and physical therapy evaluations may be needed to evaluate sensory and/or motor difficulties. Sleep is also an important variable to assess.

Table 30-4 Medical and Genetic Evaluation of Children with Autism Spectrum Disorder

Recommended evaluations
Careful physical examination to identify dysmorphic physical features
Macrocephaly
Wood's lamp examination for tuberous sclerosis
Formal audiologic evaluation
Lead test; repeat periodically in children with pica
Chromosomal microarray
Consider if results of above evaluation are normal and if accompanying intellectual impairment
FISH test for region 15q11q13 to rule out duplications in Prader-Willi/Angelman syndrome
Fluorescence in situ hybridization (FISH) test for telomeric abnormalities
Test for mutations in *MECP2* gene (Rett syndrome) in females
DNA testing for fragile X syndrome
Metabolic testing to consider based on clinical features (emesis, hypotonia, lethargy, ataxia, coarse facial features of a storage disease, multiple organs involved)
Fasting blood glucose
Plasma amino acids
Ammonia and lactate
Fatty acid profile, paroxysmal
Carnitine
Acylcarnitine, quantitative
Homocysteine
Urine amino acids
Urine organic acids
Urine purine/pyrimidines
Urine acylglycine, random
Plasma 7-dehydrocholesterol (Smith-Lemli-Opitz disease screening)
Medical testing to consider based on clinical features
Complete blood cell count
Liver enzymes
Biotinidase
Thyroxine, thyroid-stimulating hormone
Ceruloplasmin/serum copper
EEG if the following clinical features are noted
Clinically observable seizures
History of significant regression in social or communication functioning

Adapted from Barbaresi WJ, Katusic SK, Voigt R. Autism: A review of the state of the science for pediatric primary care clinicians, Arch Pediatr Adolesc Med *160:1169-1175, 2006.*

TREATMENT

The pediatric practitioner should aim to foster a long-term collaborative relationship with the family that will vary in intensity over time. For young children, diagnosis and identification of treatment programs will generally be the major focus, whereas for school age children behavioral and medication issues will often become a priority. Vocational training along with future self-sufficiency planning becomes critical in adolescence and early adulthood. It is helpful to the family for the pediatric practitioner to maintain an active role in long-term treatment planning, providing family support, and navigating the healthcare and educational systems.

Psychosocial Interventions

Structured behavioral, educational, and communication interventions are effective for many children with ASD and are associated with better outcomes. Several comprehensive treatment approaches are effective for certain groups of children, although none of the approaches has clearly emerged as superior.

***Applied behavioral analysis* (ABA)** is a behavioral intervention that is informed by basic and empirically supported learning principles. A widely disseminated comprehensive ABA program is *Early Intensive Behavioral Intervention*. Early Intensive Behavioral Intervention is intensive and highly individualized with up to 40 hr per week of one-to-one direct teaching, initially using discrete trials to teach simple skills and progressing to more complex skills such as initiating verbal behavior. ABA techniques have efficacy for specific problem behaviors and to be effective when applied to academic tasks, adaptive living skills, communication, social skills, and vocational skills.

Older children and adolescents with relatively higher intelligence, but with poor social skills and psychiatric symptoms, can benefit from more intensive behavioral or cognitive-behavioral therapy and/or supportive psychotherapy. The focus is on achieving social communication competence, emotional and behavioral regulation, and functional adaptive skills necessary for independence.

Children with ASD need a structured educational approach with explicit teaching. Effective programs typically involve planned, intensive, individualized intervention with an experienced, interdisciplinary

Table 30-5 Level of Evidence for Pharmacologic Treatment of Target Symptoms in Autism Spectrum Disorder

CLASS	AGENT	PRIMARY TARGET SYMPTOM(S)	LEVEL OF EVIDENCE
α_2-Agonist	Clonidine	Hyperactivity	Insufficient
	Guanfacine	Hyperactivity	Insufficient
Antipsychotics	Aripiprazole	Irritability, hyperactivity, stereotypy	Established
	Haloperidol	Behavioral symptoms	Established
	Risperidone	Irritability, hyperactivity	Established
	Risperidone	Repetitive behavior, stereotypy	Preliminary
	Olanzapine	Global functioning	Insufficient
Mood stabilizers	Divalproex sodium/Valproic acid	Irritability, repetitive behavior	Insufficient
	Lamotrigine	Irritability, social behavior	Insufficient
	Levetiracetam	Irritability	Insufficient
Norepinephrine reuptake inhibitors	Atomoxetine	Hyperactivity	Preliminary
Serotonin reuptake inhibitors	Citalopram	Repetitive behavior	Insufficient
	Fluoxetine	Repetitive behavior	Insufficient
	Clomipramine	Repetitive behavior, stereotypy, irritability, hyperactivity	Insufficient
Stimulants	Methylphenidate	Hyperactivity	Promising
Miscellaneous	Amantadine	Hyperactivity, irritability	Insufficient
	Naltrexone	Social behavior, communication, Indiscriminant learning, SIB	Insufficient
	Naltrexone	Hyperactivity	Preliminary
	Pentoxifylline	Irritability, social withdrawal	Preliminary

Established, >2 strong studies or >4 adequate studies in separate settings; Insufficient, lack of research or mixed outcomes; Preliminary, >1 adequate study; Promising, >2 adequate studies.

Adapted from Siegel M, Beaulieu AA. Psychotropic medications in child with autism spectrum disorders: A systematic review and synthesis for evidenced based practice. J Autism Dev Disord *42(8):1592–1605, 2012.*

team of providers, and family involvement to ensure generalization of skills. Two structured educational models with demonstrated efficacy include the *Early Start Denver Model* and the *Treatment and Education of Autism and related Communication handicapped Children* (TEACCH) program. The ***individualized educational plan*** **(IEP)** should reflect an accurate assessment of the child's strengths and vulnerabilities with an explicit description of services to be provided, goals and objectives, and procedures for monitoring effectiveness. Development of an appropriate IEP is central in providing effective service to the child and family.

Communication is generally addressed in the child's IEP in coordination with the speech-language pathologist. Children who do not yet use words can be helped through use of alternative communication modalities such as sign language, electronic communication boards, visual supports, picture exchange, and other forms of augmentative communication. For individuals with fluent speech, the focus should be on pragmatic (social) language skills training.

There is a lack of evidence for most other forms of psychosocial intervention. Studies of sensory-oriented interventions, such as auditory integration training, sensory integration therapy, and touch therapy/massage have contained methodologic flaws and have yet to show replicable improvements. There is also limited evidence thus far for what are usually termed developmental, social-pragmatic models of intervention. Children with ASD are psychiatrically hospitalized at substantially higher rates than the non-ASD population. The efficacy of this level of care is unknown, although there is preliminary evidence for the efficacy of hospital psychiatry units that specialize in this population.

Pharmacotherapy

Pharmacologic interventions (Table 30-5) may increase the ability of children with ASD to benefit from educational and other interventions as well as to remain in less-restrictive environments through the management of challenging behavior. Common targets for pharmacologic intervention include associated comorbid conditions (anxiety, depression) and problematic target symptoms (e.g., irritability, hyperactivity, repetitive behavior, stereotypy, self-injurious behavior).

The FDA has approved risperidone (ages 5-16 yr) and aripiprazole (ages 6-17 yr) for the treatment of irritability in ASD, as evidenced by physical aggression, self-injury, and severe tantrum behavior. In youth weighing < 20 kg, the initial dose of risperidone is 0.25 mg/day with a target dose of 0.5 mg/day, and maximum does of 3 mg/day. In those weighing ≥ 20 kg, the initial dose of risperidone is 0.5 mg/day with a target dose of 1 mg/day, and maximum dose of 3 mg/day. For aripiprazole, the initial dose is 2 mg/day with a target dose of 5-10 mg/day, and maximum dose of 15 mg/day.

The atypical antipsychotic agents also reduce hyperactivity in ASD, though stimulants and atomoxetine appear to be promising for hyperactivity. There is also evidence that repetitive behaviors and stereotypies in ASD may respond to the antipsychotics. Selective serotonin reuptake inhibitors do not have evidence supporting their use for repetitive behaviors or irritability in ASD; they may have efficacy for the treatment of co-occurring depressive and anxiety disorders. The doses of these latter medications would parallel clinical prescribing practices for the specific target symptom (hyperactivity) and/or mental disorders. There is insufficient evidence to support the use of mood stabilizers.

Combining medication with parent training appears to be moderately more efficacious than medication alone for reducing serious behavioral disturbance, and modestly more efficacious for adaptive functioning. Individuals with ASD may be non-verbal, so response to medication is often judged by caregiver report. While this may help assess the effectiveness of the selected medication, it must be remembered that the overall goal of pharmacotherapy is to facilitate the child's adjustment and engagement with behavioral, educational, and communication interventions.

Intranasal oxytocin (IO) is a novel approach to treating ASD. In preliminary studies, IO leads to increased social interactions, better speech comprehension, reduced repetitive behaviors, and functional MRI evidence of improved social attunement. There is currently a large clinical trial testing the efficacy of IO.

Chapter 31

Childhood Psychoses

Giuseppe J. Raviola, Michael L. Trieu, David R. DeMaso, and Heather J. Walter

Psychosis is a severe disruption of thought, perception, and behavior resulting in **loss of reality testing.** Delusions, hallucinations, disorganized thinking, grossly disorganized behavior, and negative symptoms are key features that define psychotic disorders. **Delusions** are fixed, unchangeable, false beliefs even in light of conflicting evidence. They may include a variety of themes (persecutory, referential, somatic, religious, or grandiose). Delusions are considered bizarre if they are clearly implausible. **Hallucinations** are vivid and clear perception-like experiences that occur without external stimulus and have the full force and impact of normal perceptions. They may occur in any sensory modality; auditory hallucinations are the most common. **Disorganized thinking** is typically inferred from an individual's speech (loose associations, tangentiality, or incoherence). **Grossly disorganized behavior** may range from child-like silliness to catatonic behavior. **Negative symptoms** include diminished emotional expression, avolition, alogia (lack of speech), anhedonia (inability to experience pleasure), and asociality. They generally account for a substantial portion of the morbidity associated with schizophrenia.

31.1 Schizophrenia Spectrum and Other Psychotic Disorders

Giuseppe J. Raviola, Michael L. Trieu, David R. DeMaso, and Heather J. Walter

Schizophrenia spectrum and other psychotic disorders include brief psychotic disorder, schizophreniform disorder, schizophrenia, schizoaffective disorder, substance/medication-induced psychotic disorder (see Chapter 114), psychotic disorder caused by another medical condition, catatonia associated with another mental disorder, catatonic disorder caused by another medical condition, unspecified catatonia, delusional disorder, schizotypal personality disorder, and other specified/unspecified schizophrenia spectrum and other psychotic disorders.

DESCRIPTION

The schizophrenia spectrum and other psychotic disorders are primarily characterized by the active (or positive) symptoms of psychosis, specifically delusions, hallucinations, disorganized speech, or grossly disorganized behavior. **Brief psychotic disorder** is characterized by the sudden onset (within 2 wk from baseline function) of these symptoms in the context of emotional turmoil or overwhelming confusion, followed by complete resolution (Table 31-1). Although brief, the level of impairment in this disorder may be severe enough that supervision may be required to ensure that basic needs are met and the individual is protected from the consequences of poor judgment and cognitive impairment.

If the psychotic symptoms persist for up to 6 mo, the condition is called **schizophreniform disorder** (Table 31-2), whereas in **schizophrenia**, there are continuous signs of the disturbance for at least 6 mo (Table 31-3). Active symptoms must have been present for a significant portion of time during a 1 mo period, and the level of psychosocial functioning must be markedly below the level achieved prior to the onset (or there is failure in children to achieve the expected level of functioning).

Table 31-1 DSM-5 Diagnostic Criteria for Brief Psychotic Disorder

A. Presence of 1 (or more) of the following symptoms. At least 1 of these must be (1), (2), or (3):
   1. Delusions.
   2. Hallucinations.
   3. Disorganized speech (e.g., frequent derailment or incoherence).
   4. Grossly disorganized or catatonic behavior.

   Note: Do not include a symptom if it is a culturally sanctioned response.

B. Duration of an episode of the disturbance is at least 1 day but less than 1 mo, with eventual full return to premorbid level of functioning.

C. The disturbance is not better explained by major depressive or bipolar disorder with psychotic features or another psychotic disorder such as schizophrenia or catatonia, and is not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication) or another medical condition.

Specify if:

With marked stressor(s) (brief reactive psychosis): If symptoms occur in response to events that, singly or together, would be markedly stressful to almost anyone in similar circumstances in the individual's culture.

Without marked stressor(s): If the symptoms do not occur in response to events that, singly or together, would be would be markedly stressful to almost anyone in similar circumstances in the individual's culture.

With postpartum onset: If onset is during pregnancy or within 4 wk postpartum.

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, p. 94.

Table 31-2 DSM-5 Diagnostic Criteria for Schizophreniform Disorder

A. Two (or more) of the following, each present for a significant portion of time during a 1 mo period (or less if successfully treated). At least 1 of these must be (1), (2), or (3):
   1. Delusions.
   2. Hallucinations.
   3. Disorganized speech (e.g., frequent derailment or incoherence).
   4. Grossly disorganized or catatonic behavior.
   5. Negative symptoms (i.e., diminished emotional expression or avolition).

B. An episode of the disorder lasts at least 1 mo but less than 6 mo. When the diagnosis must be made without waiting for recovery, it should qualified as "provisional."

C. Schizoaffective disorder and depressive or bipolar disorder with psychotic features have been ruled out because either (1) no major depressive or manic episodes have occurred concurrently with the active-phase symptoms; or (2) if mood episodes have occurred during active-phase symptoms, they have been present for a minority of the total duration of the active and residual periods of the illness.

D. The disturbance is not attributable to the physiological effects of a substance (e.g., a drug of abuse, a medication) or another medical condition.

Specify if:

With good prognostic features: This specifier requires the presence of at least 2 of the following features: onset of prominent psychotic symptoms within 4 wk of the first noticeable change in usual behavior or functioning; confusion or perplexity; good premorbid social and occupational functioning; and absence of blunted or flat affect.

Without good prognostic features: This specifier is applied if 2 or more of the above features have not been present.

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, pp. 96–97.

Table 31-3	DSM-5 Diagnostic Criteria for Schizophrenia

A. Two (or more) of the following, each present for a significant portion of time during a 1 mo period (or less if successfully treated). At least 1 of these must be (1), (2), or (3):
 1. Delusions.
 2. Hallucinations.
 3. Disorganized speech (e.g., frequent derailment or incoherence).
 4. Grossly disorganized or catatonic behavior.
 5. Negative symptoms (i.e., diminished emotional expression or avolition).

B. For a significant portion of the time since the onset of the disturbance, level of functioning in 1 or more major areas, such as work, interpersonal relations, or self-care, is markedly below the level achieved prior to the onset (or when the onset is in childhood or adolescence, there is failure to achieve expected level of interpersonal, academic, or occupational functioning).

C. Continuous signs of the disturbance persist for at least 6 mo. This 6 mo period must include at least 1 mo of symptoms (or less if successfully treated) that meet criterion A (i.e., active-phase symptoms) and may include periods of prodromal or residual symptoms. During these prodromal or residual periods, the signs of the disturbance may be manifested by only negative symptoms or by two or more symptoms listed in criterion A present in an attenuated form (e.g., odd beliefs, unusual perceptual experiences).

D. Schizoaffective disorder and depressive or bipolar disorder with psychotic features have been ruled out because either (1) no major depressive or manic episodes have occurred concurrently with the active-phase symptoms; or (2) if mood episodes have occurred during active-phase symptoms, they have been present for a minority of the total duration of the active and residual periods of the illness.

E. The disturbance is not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication) or another medical condition.

F. If there is a history of autism spectrum disorder or a communication disorder of childhood onset, the additional diagnosis of schizophrenia is made only if prominent delusions or hallucinations, in addition to the other required symptoms of schizophrenia, are also present for at least a month (or less if successfully treated).

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, pp. 99–100.

Table 31-4	Medical Conditions Associated with Psychotic-like Behavior

Medications (steroids, β-blocking agents, cyclosporine)
Drugs of abuse (intoxication, overdose or withdrawal)
Central nervous system infections
Autoimmune encephalitis (anti–*N*-methyl-D-aspartate [NMDA] receptor/limbic/paraneoplastic)
Acute disseminated encephalomyelitis (ADEM)
Systemic lupus erythematosus (SLE)
Syndromes (fragile X, trisomy 21, tuberous sclerosis)
Wilson disease
Porphyria
Nonconvulsive status (seizures)
Hyper-/hypoparathyroidism
Hyper-/hypothyroidism
Hyper-/hypoadrenalism
Hypoglycemia
Thiamine deficiency
Vitamin B_{12} deficiency
Inborn errors of metabolism (see Table 31-5)

Schizophrenia is a heterogeneous clinical syndrome with a range of cognitive, behavioral, and emotional dysfunctions. Prodromal symptoms often precede the active phase, in which individuals may express a variety of unusual or odd beliefs and may have unusual perceptual experiences; their speech may be generally understandable but vague; and their behavior may be unusual but not grossly disorganized. Individuals who had been socially active may become withdrawn.

Individuals with schizophrenia can display inappropriate affect, dysphoric moods, disturbed sleep patterns, and lack of interest in eating or food refusal. Depersonalization, derealization, somatic concerns, and anxiety and phobias are common. Cognitive deficits are observed, including decrements in declarative memory, working memory, language function, and other executive functions, as well as slower processing speed. These individuals may have no insight or awareness of their disorder, which is a predictor of nonadherence to treatment, higher relapse rates, and poorer illness course. Hostility and aggression can be associated with schizophrenia, although spontaneous or random assault is uncommon. Aggression is more frequent for younger males and for individuals with a past history of violence, non-adherence with treatment, substance abuse, and impulsivity.

The essential features of schizophrenia are the same in childhood, but it is more difficult to make the diagnosis. In children, delusions and hallucinations may be less elaborate, and visual hallucinations may be more common. Disorganized speech and behavior occur in many childhood onset psychiatric disorders, and should not be attributed to schizophrenia unless more common disorders are ruled out.

EPIDEMIOLOGY

Brief psychotic disorders have been reported to account for 9% of cases of first-onset psychosis in the United States with a 2 : 1 ratio in favor of females. The incidence of schizophreniform disorders in the United States and other developed countries appears as much as 5-fold less than that of schizophrenia, whereas in developing countries the incidence is higher (approaching that of schizophrenia), particularly when associated with good prognostic features.

The lifetime prevalence of schizophrenia is approximately 0.3-0.7%, although there are reported variations by race/ethnicity, across countries, and by geographic origin for immigrants. The male : female ratio is approximately 1.4 : 1. Males generally have a worse premorbid adjustment, lower educational achievement, more prominent negative symptoms, and more cognitive impairment than females.

CLINICAL COURSE

Brief psychotic disorder may appear in adolescence or early adulthood, with the average age of onset in the mid-30s. By definition, a diagnosis of brief psychotic disorder requires full remission within 1 mo of onset. The development of schizophreniform disorder is similar to that of schizophrenia. About one-third of individuals with an initial diagnosis of schizophreniform disorder recover within a 6 mo period; the majority of the remaining two-thirds will eventually receive a diagnosis of schizophrenia or schizoaffective disorder.

Schizophrenia typically develops between the late teens and the mid-30s; onset prior to adolescence is rare. The peak age at onset for the first psychotic episode is in the early to mid-20s for males and in the late-20s for females. The onset may be abrupt or insidious, but the majority of individuals manifest a slow and gradual development, with around one-half of individuals complaining of depressive symptoms. The predictors of course and outcome are largely unexplained. The course appears to be favorable in approximately 20% of cases, and a small number of individuals are reported to recover completely. Most individuals require daily living supports. Psychotic symptoms tend to diminish over time, while negative symptoms are the most persistent, along with cognitive deficits.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis for the psychotic disorders is broad, and includes substances/medications (dextromethorphan, LSD, hallucinogenic mushrooms, psilocybin, peyote, cannabis, stimulants, and inhalants; corticosteroids, anesthetics, anticholinergics, antihistamines, amphetamines), other medical conditions (Tables 31-4 and 31-5), other disorders within the same class, depressive and bipolar disorders

Table 31-5 Psychiatric Signs in Inborn Errors of Metabolism in Adolescents and Adults: Review of the Literature and Personal Experience

	CONFUSION	MENTAL RETARDATION	BEHAVIORAL DISTURBANCES	CATATONIA	VISUAL HALLUCINATIONS	PSYCHOSIS (SCHIZOPHRENIA)	DEPRESSION

From Sedel F, Baumann N, Turpin JC, et al: Psychiatric manifestations revealing inborn errors of metabolism in adolescent and adults. J Inherit Metab Dis *30:631–641, 2007, Table 3, p. 635.*

(see Chapter 26), malingering and factitious disorders, obsessive-compulsive (see Chapter 25) and body dysmorphic disorder, posttraumatic stress disorder (see Chapter 25), autism spectrum disorder (see Chapter 30) or other communication disorders (see Chapter 35), and personality disorders.

Autoimmune encephalitis caused by anti–*N*-methyl-D-aspartate (NMDA) receptor or other autoantibodies may manifest with psychosis, anxiety, depression, agitation, aggression, delusions, catatonia, hallucinations, and paranoia in combination with sleep disturbances, autonomic dysfunction (hypoventilation), dyskinesias, movement disorders, seizures, and a depressed level of consciousness. The electroencephalogram (EEG), cerebral spinal fluid, and MRI are usually, but not always, abnormal. The constellation of psychosis and encephalitic features should suggest the diagnosis; however, at presentation behavioral problems may be the dominant feature (see Chapter 598.4).

Differentiating medical from psychiatric causes of abnormal behavior may be difficult. In general, medical causes are often associated with abnormalities in vital signs and the neurologic exam (including level of consciousness). In medical causes of abnormal behavior, there may not be a positive family history or a prior personal history of psychiatric illness. Furthermore, in medical causes, there are often impairments in attention, orientation, recent memory, and intellectual function. Hallucinations may be present with medical disease, but they are often tactile, visual, or olfactory rather than auditory (noted in psychiatric disease). Medical patients may be able to reality test about their hallucinations, stating they are aware they are not real.

The diagnosis of a psychotic disorder should be made only after these other explanations for the observed symptoms have been ruled out. Most children who report hallucinations do not meet criteria for the schizophrenia spectrum disorders, and most do not have psychosis. Normative childhood experiences, including overactive imaginations and vivid fantasies, can be mistaken for psychosis.

COMORBIDITY

Rates of comorbidity with substance-related disorders are high in schizophrenia. Other common comorbidities are anxiety disorders and obsessive-compulsive disorders.

SEQUELAE

Follow-up studies of early onset schizophrenia suggest moderate to severe impairment across the life span. Poor outcome is predicted by low premorbid functioning, insidious onset, higher rates of negative symptoms, childhood onset, and low intellectual functioning. When followed into adulthood, youth with schizophrenia demonstrated greater social deficits, lower levels of employment, and were less likely to live independently, relative to those with other childhood psychotic disorders.

Approximately 5-6% of individuals with schizophrenia die by suicide, approximately 20% attempt suicide on 1 or more occasions, and many more have suicidal ideation. Life expectancy is reduced in individuals with schizophrenia because of associated medical conditions; a shared vulnerability for psychosis and medical disorders may explain some of the medical comorbidity of schizophrenia.

ETIOLOGY AND RISK FACTORS

Etiologic evidence for schizophrenia supports a neurodevelopmental and neurodegenerative model with multiple genetic and environmental exposures playing important roles. It has been hypothesized that while psychotic disorders likely have their origins in early development, but it is not until they are in their mid-teens that the underlying neural structures manifest the disabling functional deficits and resultant psychotic symptoms.

Genetic Factors

The lifetime risk of developing schizophrenia is 5-20 times higher in 1st-degree relatives of affected probands compared to the general population. Concordance rates of 40-60% and 5-15% have been reported, respectively, in monozygotic and dizygotic twins. Genome-wide association studies, using large collaborative international cohorts, have implicated different genomic loci and genes, including the major histocompatibility complex (6p21.1), MIR137, and ZNF804a. Structural mutations arising at genomic "hotspots," including 1q21.1, 15q13.3, and 22q11.2, may be responsible for 0.5-1.0% of cases.

Childhood schizophrenia appears to be associated with a higher rate of large cytogenetic abnormalities and rare structural variants than reported in adults. The majority of rare copy number errors detected in affected persons are found at different genetic loci, and many are unique to 1 individual or family.

Environmental Factors

In utero exposure to maternal famine, advanced paternal age, prenatal infections, obstetric complications, marijuana use and immigration have been hypothesized to contribute to the development of schizophrenia. Environmental exposures may mediate disease risk via direct neurologic damage, gene by environment interactions, epigenetic effects and/or de novo mutations. There is no evidence that psychological or social factors cause schizophrenia. Rather, environmental factors may potentially interact with biologic risk factors to mediate the timing of onset, course, and severity of the disorder. Expressed emotion within the family setting can influence the onset and/or exacerbation of acute episodes and relapse rates.

Neuroanatomical Abnormalities

Increased lateral ventricle volumes along with reductions in hippocampus, thalamus, and frontal lobe volumes have been reported in schizophrenia. Youth in particular have reductions in grey matter volumes and reduced cortical folding. Neurotransmitter systems, particularly central nervous system dopamine circuits, are hypothesized to have a key role in the pathophysiology of schizophrenia. The dopamine hypothesis is derived in part from the identification of D_2 receptor blockade as the mechanism for the action of antipsychotic medications.

PREVENTION

There has been significant interest in prospectively identifying youth at risk for schizophrenia spectrum and other psychotic disorders in an effort to provide early intervention prior to the development of a full-blown psychotic disorder. Various names including ***attenuated psychosis syndrome*** **(APS)**, psychosis risk syndrome, ultrahigh risk, clinical high risk, at-risk mental state, and prodromal stage have been used to describe patients that present with troubling symptoms suggestive of early psychosis.

APS is characterized by the presence of delusions, hallucinations, or disorganized speech in an attenuated form, with relatively intact reality testing, but of sufficient frequency to warrant clinical attention. The symptoms are described as being present at least once per week for the past month and have begun/worsened over the past year. The symptoms are less severe and more transient than a psychotic disorder, although nearly 20-40% with these attenuated symptoms appear to go on to a psychotic disorder within 3 yr of symptom presentation. There is evidence that premorbid lower cognitive and social skills as well as a history of substance abuse contribute to the risk of developing a full-blown psychotic disorder in individuals with APS.

There is some evidence that antipsychotic medication may delay conversion of attenuated to full-blown psychosis and ameliorate attenuated symptoms in active treatment, yet there appear to be no lasting effects after the medication is withdrawn. In addition, there is concern that the long-term use of even low-dose antipsychotic medication may cause heightened sensitization of brain dopamine receptors, which, in turn, could lead to a rapid-onset of psychosis following discontinuation of the medication.

Antidepressants have been associated with symptomatic improvement in adolescents with APS. In a randomized control trial, omega-3 fish oils reduced attenuated positive, negative, and general symptoms. Psychological interventions (social skills, cognitive, and interaction training programs, as well as psychoeducational family interventions and cognitive-behavioral therapy) are reported to improve symptoms and psychosocial functioning in youth with early symptoms.

Despite improvements in diagnostic predictive validity, significant concern remains regarding a high false-positive rate (identifying an individual as prodromal who does not go on to develop psychosis) that may cause individuals to be stigmatized or exposed to unnecessary treatment. In this context, youth with early symptoms suggestive of psychosis should be referred to a child and adolescent psychiatrist and/or a specialized research program.

SCREENING/CASE FINDING

Pediatric practitioners can make general inquiries of youth and their parents regarding problems with thinking or perceptions. For the older youth, questions like *"Does your mind ever play tricks on you?," "Do you hear voices talking to you when no one is there?," and/or "Does your mind ever feel confused?"* can help elicit symptoms. For younger children, the clinician must ensure that the child understands the questions. True psychotic symptoms are generally confusing to the individual, and highly descriptive, detailed, organized, and/or situation-specific reports are less likely to represent true psychosis. Overt signs of the illness should be evident on mental status exam; without overt evidence of psychosis, the validity of symptom reports needs to be carefully scrutinized. For youth presenting with what could be psychosis, assessment and treatment in the specialty mental health setting by a child and adolescent psychiatrist should be provided.

ASSESSMENT

The diagnostic assessment of schizophrenia in youth is uniquely complicated and misdiagnosis is common. Most children who report hallucinations do not meet criteria for schizophrenia, and many do not have a psychotic illness. Normative childhood experiences, including overactive imaginations and vivid fantasies, can be misinterpreted as psychosis. Expertise in childhood psychopathology and experience in assessing reports of psychotic symptoms in youth are important prerequisite skills for clinicians evaluating youth for possible psychosis. Comprehensive diagnostic assessments, which reconcile mental status findings with the rigorous application of diagnostic criteria, help improve accuracy.

There are no neuroimaging, psychological or laboratory tests that establish a diagnosis of schizophrenic spectrum disorders. The medical evaluation focuses on ruling out nonpsychiatric causes of psychosis, while also establishing baseline laboratory parameters for monitoring medication therapy. Routine laboratory testing typically includes blood counts, basic metabolic panel, liver and renal functions, metabolic parameters, and thyroid functions. More extensive evaluation is indicated for atypical presentations, such as a gross deterioration in cognitive and motor abilities, focal neurologic symptoms, or delirium. Neuroimaging may be indicated when neurologic symptoms are present, or an EEG is indicated for a clinical history suggestive of seizures. Toxicology screens are indicated for acute onset or exacerbations of psychosis, when exposure to drugs of abuse cannot be ruled out. Genetic testing is indicated if there are associated dysmorphic or syndromic features. Tests to rule out specific syndromes or diseases (e.g., amino acid screens for inborn errors of metabolism, ceruloplasmin for Wilson disease [see Chapter 357.2], porphobilinogen for acute intermittent porphyria [see Chapter 91]) are indicated for clinical presentations suggestive of a specific syndrome. Neuropsychological testing cannot establish the diagnosis, but may be important for documenting cognitive deficits for academic planning.

TREATMENT

There are hallmark phases important to recognize in the assessment and management of schizophrenia. In the prodrome phase, most patients experience functional deteriorations (i.e., social withdrawal, idiosyncratic preoccupations, unusual behaviors, academic failure, deteriorating self-care skills, and/or dysphoria) prior to the onset of psychotic symptoms. The acute phase is characterized by prominent positive symptoms and deterioration in functioning. The recuperative/recovery phase is marked by a several-month period of impairment and predominantly negative symptoms. The residual phase (if reached) has no positive symptoms though negative symptoms may contribute to some level of impairment.

Treatment goals include decreasing psychotic symptomology, directing the child toward a developmentally typical trajectory, and reintegrating the child into the home and community. Children and families facing schizophrenia spectrum disorders require an array of mental health services to address their psychological, social, educational, and cultural needs. Given the insidious onset and chronic course of these disorders, the patient must be followed longitudinally, with periodic reassessment to hone diagnostic accuracy and tailor services to meet the patient's and family's needs. Integrated psychopharmacologic, psychotherapeutic, psychoeducational, and case-management services are often necessary.

Psychoeducation about the illness with an assessment of the potential role of stigma in treatment participation is critical for improving adherence with treatment recommendations. Assessing a child's strengths and vulnerabilities as well as available environmental resources is critical in devising an effective treatment plan. School and community liaison work to develop and maintain a day-to-day schedule for the patient is important. Specialized educational programs should be considered within the school system. Cognitive remediation has shown some promising results in planning ability and cognitive flexibility. Effective and collaborative communication among the family, the pediatrician, a child and adolescent psychiatrist, and other mental health providers increases the potential for the patient's optimal functioning.

Pharmacotherapy

First-generation (typical) and second-generation (atypical) antipsychotic medications have been shown to be effective in reducing psychotic symptoms with the latter the preferred medication choice (see Chapter 21). Haloperidol, risperidone, aripiprazole, quetiapine, paliperidone, and olanzapine are FDA approved for treating schizophrenia in ages 13 yr and older. The choice of which agent to use first is typically based on FDA approval status, side-effect profile, patient and family preference, clinician familiarity, and cost. Depot antipsychotics have not been studied in pediatric age groups and have inherent risks with long-term exposure to side effects. Although clozapine is effective in treating both positive and negative symptoms, its risk for agranulocytosis and seizures limits its use to those patients with treatment-resistant disorders.

Most patients require long-term treatment and are at significant risk to relapse if their medication is discontinued. The goal is to maintain the medication at the lowest effective dose so as to minimize potential adverse events. Many patients will continue to experience some degree of positive or negative symptoms, requiring ongoing treatment. Patients should maintain regular physician contact so as to monitor symptom course, side effects, and adherence.

Individuals prescribed antipsychotic medications need to be systematically monitored for side effects, including sedation, abnormal movements, weight gain, hyperprolactinemia, elevated liver transaminases, diabetes, hyperlipidemia, hematologic effects (leukopenia or neutropenia), seizures, neuroleptic malignant syndrome, and cardiovascular effects. For atypical antipsychotics, body mass index, fasting blood glucose, fasting triglycerides/cholesterol, waist circumference, high-density lipoprotein/low-density lipoprotein, blood pressure, and symptoms of diabetes should be checked at baseline and at regular intervals thereafter. Regular physical activity and nutritional balance should be part of a comprehensive treatment plan.

Abnormal movements (dystonia, akathisia, tardive dyskinesia) need periodic assessment preferably using a standardized instrument such as the *Abnormal Involuntary Movement Scale* (AIMS). The need for antiparkinsonian agents may be a consideration for patients, particularly those at risk for acute dystonia or who have a previous history of dystonic reactions. In patients with a personal or family history of cardiac abnormalities, including syncope, palpitations, arrhythmias, or sudden unexplained death, a baseline electrocardiogram with subsequent monitoring should be considered, along with cardiology consultation. Alternative pharmacology should be considered if the resting

heart rate exceeds 130 beats/min, or the PR, QRS, and QTc exceed 200, 120, and 460 msec, respectively.

Electroconvulsive therapy (ECT) may be used with severely impaired adolescents if medications are either not helpful or cannot be tolerated. It has not been systematically studied in children.

31.2 Psychosis Associated with Epilepsy

David R. DeMaso

Schizophrenia spectrum and other psychotic disorders include *psychotic disorder due to another medical condition* (Table 31-6). *Psychosis associated with epilepsy* has been reported in children and adults. Also called *schizophrenic-like psychosis of epilepsy*, the disorder manifests with delusions or hallucinations, along with poor insight. The characterization is complicated by the fact that anticonvulsant drugs can present with psychosis and antipsychotic drugs can lower the seizure threshold, producing seizures.

Psychosis associated with epilepsy can be further differentiated into ictal, interictal, and postictal psychosis. Ictal-induced psychosis is a form of **nonconvulsive status epilepticus**, usually complex partial status that can last for hours to days and is associated with periods of impaired consciousness. Brief interictal psychosis can last days to weeks and is associated with paranoia, delusions, and auditory hallucinations. Chronic interictal psychosis resembles schizophrenia and manifests with paranoia, visual hallucinations, and catatonia. Postictal psychosis is the most common type (observed in 2-7% of patients with epilepsy); it lasts up to 1 wk and then spontaneously remits.

The diagnosis requires a strong index of suspicion and EEG monitoring. Treatment requires appropriate anticonvulsant drugs and, if the psychosis persists, initiating low-dose antipsychotic medication.

31.3 Catatonia in Children and Adolescents

Bonita F. Stanton

Catatonia is a poorly defined state presenting as an unusual manifestation of decreased or increased muscle tone and decreased responsiveness (although agitation may be present) occurring in association with a broad array of conditions affecting children, adolescents and adults. These conditions include psychosis, autism spectrum disorder, developmental disorders, drug-induced conditions, affective disorders and a wide range of medical disorders (Table 31-7). Not surprising given the ill-defined nature of the condition, the prevalence of catatonia in children and adolescents is unknown, although it is generally believed to be significantly underdiagnosed. Recognition of catatonia by a clinician is very important because the disorder is generally very responsive to treatment with benzodiazepines and/or ECT.

DIAGNOSIS AND TREATMENT

Catatonia is defined as 3 or more of the 12 symptoms listed in Table 31-8. An important next step is the evaluation and possible elimination of medications being administered to the child for their potential to induce catatonic symptoms, a not-infrequent side effect of many medical and psychiatric medications. Of particular importance, antipsychotic agents should be discontinued as they have been associated with an increased incidence of malignant catatonia or neuroleptic malignant syndrome (see Chapter 21).

Benzodiazepams (typically lorazepam) and **ECT** are effective in adults and appear to be effective in children. A treatment algorithm using a lorazepam challenge test (by mouth, intravenous, or intramuscular administration of lorazepam 1-2 mg) is shown in Figure 31-1. If the challenge test does reverse symptoms, increasing doses of lorazepam are indicated, with careful monitoring to avoid side effects. ECT may be indicated alone (if no improvement with lorazepam) or in combination with lorazepam if some but incomplete improvement is noted.

Table 31-6 DSM-5 Diagnostic Criteria for Psychotic Disorder Due to Another Medical Condition

A. Prominent hallucinations or delusions.
B. There is evidence from the history, physical examination, or laboratory findings that the disturbance is the direct pathophysiological consequence of another medical condition.
C. The disturbance is not better explained by another mental disorder.
D. The disturbance does not occur exclusively during the course of a delirium.
E. The disturbance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning.

Specify whether:

With delusions: If delusions are the predominant symptom.
With hallucinations: If hallucinations are the predominant symptom.

Table 31-7 Conditions Associated with Catatonia

Psychotic disorders
- Paranoid schizophrenia, catatonic schizophrenia, psychosis, autism, Prader-Willi syndrome, intellectual impairment

Mood disorders
- Bipolar disorder- manic or mixed episodes

Major depressive disorder

Medical conditions
- Endocrine abnormalities, infections, electrolyte imbalances

Neurologic conditions
- Epilepsy, strokes, traumatic brain injury, multiple sclerosis, encephalitis

Drugs
- Withdrawal: Benzodiazepines, L-dopa, gabapentin
- Overdose: LSD, phencyclidine (PCP), cocaine, Ecstasy, disulfiram, levetiracetam

Adapted from Weder ND, Muralee S, Penland H, Tampi RR: Catatonia: a review. Ann Clin Psychiatry *20(2):97–107, 2008, Table 2.*

Table 31-8 Diagnostic Criteria of Catatonia in the DSM-5

Catatonia is defined as the presence of 3 or more of the following

1. Catalepsy (i.e., passive induction of a posture held against gravity)
2. Waxy flexibility (i.e., slight and even resistance to positioning by examiner)
3. Stupor (no psychomotor activity; not actively relating to environment)
4. Agitation, not influenced by external stimuli
5. Mutism (i.e., no, or very little, verbal response [*Note:* not applicable if there is an established aphasia])
6. Negativism (i.e., opposing or not responding to instructions or external stimuli)
7. Posturing (i.e., spontaneous and active maintenance of a posture against gravity)
8. Mannerisms (i.e., odd caricature of normal actions)
9. Stereotypies (i.e., repetitive, abnormally frequent, non–goal-directed movements)
10. Grimacing
11. Echolalia (i.e., mimicking another's speech)
12. Echopraxia (i.e., mimicking another's movements)

31.4 Acute Phobic Hallucinations of Childhood

Giuseppe J. Raviola, Michael L. Trieu, David R. DeMaso, and Heather J. Walter

Among adults, hallucinations are viewed as synonymous with psychosis and as harbingers of serious psychopathology. In children, hallucinations can be part of normal development or can be associated with nonpsychotic psychopathology, psychosocial stressors, drug intoxication, or physical illness. The first clinical task in evaluating youth who report hallucinations is to sort out those that are associated with severe mental illness from those that derive from other causes (Fig. 31-2).

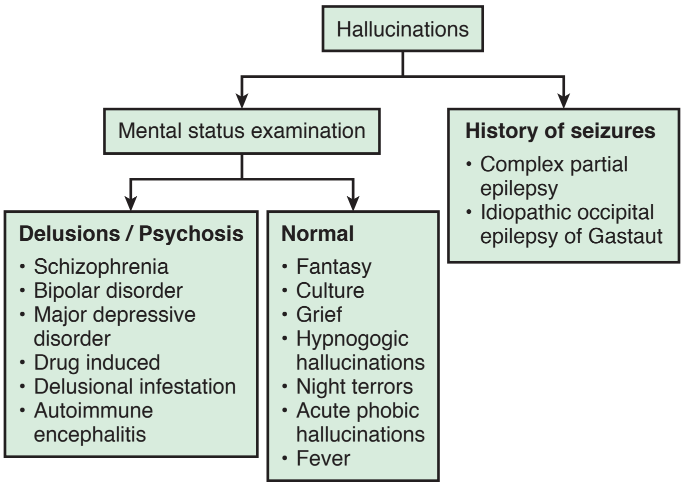

Figure 31-2 Evaluation of hallucinations.

CLINICAL MANIFESTATIONS

Hallucinations are perceptions (typically auditory, visual, tactile, or olfactory) that occur in the absence of identifiable external stimuli. Hallucinations can be further categorized as nondiagnostic (hearing footsteps, knocking, or one's name) and diagnostic (hearing 1 or more voices saying words other than one's own name).

In children with nonpsychotic hallucinations, the symptoms of psychosis are absent. Nonpsychotic hallucinations commonly occur in the context of severe traumatic stress, developmental difficulties, social and emotional deprivation, parents whose own psychopathology promotes a breakdown in the child's sense of reality, cultural beliefs in mysticism, and unresolved mourning. Auditory hallucinations of voices telling the child to do bad things may be more often associated with disruptive behavior disorders than with psychotic diagnoses. Hearing a voice invoking suicide is often associated with depression. Trauma-related auditory hallucinations are commonly associated with posttraumatic stress disorder or a brief psychotic disorder with marked stressors. The content of the hallucinations may be relevant in understanding the underlying psychopathology and/or developmental issues.

DIAGNOSIS AND DIFFERENTIAL DIAGNOSIS

Acute phobic hallucinations are benign and common and occur in previously healthy preschool children. The hallucinations are often visual or tactile, last 10-60 minutes, and occur at any time but most often at night. The child is quite frightened and might complain that bugs or snakes are crawling over him or her and attempt to remove them. The cause is unknown. The differential diagnosis includes drug overdose or poisoning, high fever, encephalitis, and psychosis. The child's fear is not alleviated by reassurance by the parents or physician, and the child is not amenable to reason. Findings on physical and mental status examinations are otherwise normal. Symptoms can persist for 1-3 days, slowly abating over 1-2 wk.

The differential diagnosis of hallucinations comprises a broad range of mental disorders, including diagnoses in which hallucinations are not the hallmark feature, but may be viewed as associated symptoms (posttraumatic stress disorder, nonpsychotic mood disorders, and disruptive, impulse-control, and conduct disorders); diagnoses that are defined by psychotic features (brief psychotic disorder, schizophrenia, major depressive or bipolar disorder with psychotic features); and at-risk clinical states (poor reality testing). In addition, other medical conditions can manifest with hallucinations, including drug intoxications (cannabis, LSD, cocaine, amphetamines, barbiturates), medication side effects (e.g., steroids, anticholinergic medications, stimulant medications), and physical illnesses (e.g., thyroid, parathyroid, and adrenal disorders; Wilson disease; electrolyte imbalances; infections; migraines; seizures; and neoplasms).

TREATMENT

The evaluation of the underlying condition directs the type of treatment needed. Nonpsychotic hallucinations suggest the need for disorder-specific psychotherapy (e.g., trauma-focused cognitive behavioral therapy for posttraumatic stress disorder) and perhaps adjunctive medication (e.g., an antidepressant for depression or anxiety, or a brief trial of antipsychotic medication for agitation). Cognitive-behavioral therapy focused on helping the youth understand the origin of the hallucinations and on developing coping strategies for stressful situations may be helpful for older children and adolescents. True psychotic hallucinations suggest the need for antipsychotic medication.

Learning Disorders

PART IV

Chapter 32

Neurodevelopmental Function and Dysfunction in the School-Age Child

Desmond P. Kelly and Mindo J. Natale

TERMINOLOGY AND EPIDEMIOLOGY

A **neurodevelopmental function** is a basic brain process needed for learning and productivity. **Neurodevelopmental variation** refers to differences in neurodevelopmental functioning. Wide variations in these functions exist within and between individuals. These differences can change over time and need not represent pathology or abnormality.

Neurodevelopmental dysfunctions reflect disruptions of neuroanatomic structure or psychophysiologic function and place a child at-risk for developmental, cognitive, emotional, behavioral, psychosocial and adaptive challenges. For the school-age child, an area of particular focus is academic skill development. Academic disorders have been diagnostically classified as **Specific Learning Disorder** (SLD) by the revised *Diagnostic and Statistical Manual of Mental Disorder Fifth Edition* (DSM-5). Changes in DSM-5 (compared to DSM-IV) involve a broadening of the diagnostic criteria in an effort to recognize factors that may interrupt the effective acquisition of academic skills that include **reading**, **written language, spelling** and **mathematics.** The *International Classification of Diseases* (ICD) of the World Health Organization, 10th Edition (ICD-10) categorizes **Specific Developmental Disorders of Scholastic Skills** that include **Reading Disorder, Spelling Disorder, Disorder of Arithmetical Skills,** and **Mixed Disorder of Scholastic Skills**. **Dyslexia** (reading disorder) is included in ICD-10 in a separate category of symbolic dysfunction. The terms, **Dyscalculia** (mathematics disorder), and **Dysgraphia** (written language disorder) are also used by investigators and clinicians, but their inclusion in diagnostic classification systems has been inconsistent and a source of some disagreement among experts.

Traditionally, the educational system has identified SLDs through the process of psychoeducational testing. Through this process, students experiencing academic problems would be evaluated psychometrically. Typical testing batteries have usually included measures of overall intelligence and academic skills. A student exhibiting a significant discrepancy between scores on tests of intelligence and tests of academic achievement could be classified as a student with an SLD, and would subsequently be eligible for Special Education Services. The degree of discrepancy required for such classification often differed between states and even between school districts. In a marked change in approach to the identification of SLDs, the reauthorization of the Individuals with Disabilities Education Act (IDEA) in 2004 introduced the Response to Intervention (RTI) model, which does not necessitate that schools use the discrepancy model for determining if a student has an SLD. Instead, schools may employ research-based intervention approaches and monitor a student's response to that intervention before initiating psychoeducational testing. This approach has been met with some disapproval, as those who challenge its effectiveness argue that the RTI model, in and of itself, should not be used to identify children with SLD. The underlying view behind this objection rests with the notion that children may fail to respond to RTI for a variety of reasons (e.g., underlying neurocognitive weakness), not just because a SLD exists.

Overall estimates of the prevalence of SLD's range from 3-10%. Some data indicate that approximately 8% of children 3-17 yr of age have, at one point, been identified as having a SLD. Prevalence estimates can vary owing to numerous factors, including differences in definitions and criteria used for classification and diagnosis, as well as differences in methods of assessment.

ETIOLOGY AND PATHOGENESIS

Neurodevelopmental dysfunction may present for any number of reasons. These include pre-/perinatal, genetic, medical, psychologic, environmental and sociocultural influences. Genes that contribute to neurodevelopmental dysfunction have been identified. Reading disorders can be both familial and heritable, and studies have linked some reading disabilities to specific gene loci on chromosomes 6 and 15. Chromosomal abnormalities can lead to unique patterns of dysfunction, such as visual–spatial deficits in girls diagnosed with Turner syndrome or language deficits in children with fragile X syndrome (see Chapter 81). Chromosome 22q11.2 deletion syndrome (DiGeorge or velocardiofacial syndrome [see Chapter 125]) is associated with predictable patterns of neurodevelopmental dysfunction, including a higher prevalence of intellectual disability, and deficits in visual–spatial processing, executive function, attention, working memory, verbal learning, arithmetic, and language with relative strengths in selected reading and spelling skills. Investigations of the neuroanatomical substrates have also yielded important information about the underlying causes of neurodevelopmental dysfunction. Multiple investigations have identified differences in the left parietotemporal and left occipitotemporal brain regions of individuals with dyslexia compared to those without reading difficulties (see Chapter 34). Studies also describe the neural circuitry, primarily in the parietal cortex, underlying mathematical competencies such as the processing of numerical magnitude, and mental arithmetic investigations support a broader role for the white matter in active learning and memory than was previously estimated.

Perinatal risk factors that are associated with neurodevelopmental dysfunction include very-low birthweight, severe intrauterine growth restriction, perinatal hypoxic–ischemia encephalopathy, and prenatal exposure to substances such as alcohol and drugs (see Chapter 96). Increased risk of academic and frontal lobe disorders also is associated with environmental toxins, including lead (see Chapter 721); drugs such as cocaine; infections such as meningitis and HIV; and brain injury secondary to intraventricular hemorrhage, periventricular leukomalacia, or head trauma.

Early psychologic trauma can result in both structural and neurochemical changes in the developing brain, which may contribute to neurodevelopmental dysfunction. Findings suggest that the effects of exposure to trauma (see Chapter 39) and/or abuse (see Chapter 40) early in the developmental course can induce disruption of the brain's regulatory system with connections in the orbitofrontal cortex, and may influence right-hemisphere function with associated risk for problems with information processing, memory, and frontal lobe related operations (e.g., focus and self-regulation). Environmental and sociocultural deprivation can lead to, or potentiate, neurodevelopmental dysfunction, which most often results from a combination of contributing factors, rather than a single cause.

CORE NEURODEVELOPMENTAL FUNCTIONS

The neurodevelopmental processes that are critical for academic success may best be understood as falling within **core neurodevelopmental domains**.

Sensory and Motor Development

Sensory development (e.g., auditory, visual, tactile, proprioceptive) begins well before birth. This neurodevelopmental process is crucial in helping children experience, understand, and manipulate their environments. Through sensory experiences, children's brains mature as new neuronal pathways are created and existing pathways are strengthened. Any interruption of this process may result in sensory-motor deficits and delays (e.g., apraxia) that can interfere with early development and academic performance.

Sensory development for the school-age child progresses in association with environmental exposure and with the development of other cognitive processes such as motor development.

There are 3 distinct, yet related, forms of neuromotor ability: graphomotor, fine motor, and gross motor coordination.

Graphomotor function refers to the specific motor aspects of written output. Several subtypes of graphomotor dysfunction significantly impede writing. Some children harbor weaknesses of visualization during writing. They have trouble picturing the configurations of letters and words as they write (orthographics). Their written output tends to be poorly legible, with inconsistent spacing between words. Others have weaknesses in orthographic memory, which interferes with their ability to recall and/or reproduce letter and number forms rapidly and accurately. They may labor over individual letters and prefer printing (manuscript) to cursive writing. Some exhibit signs of finger agnosia or weak graphomotor feedback; they have trouble localizing their fingers while they write. As a result, they need to keep their eyes very close to the page and tend to apply excessive pressure to the pencil. Others struggle with graphomotor production deficits. For these children, trouble producing the highly coordinated motor sequences needed for writing results in difficulty assigning writing roles to specific muscle groups in their hands. This phenomenon has also been described as **dyspraxic dysgraphia.** It is important to emphasize that a child may show excellent fine motor dexterity (as revealed in mechanical or artistic domains) but very poor graphomotor fluency (with labored or poorly legible writing).

For the school-age child, problems with **fine motor function** can disrupt their ability to communicate in written form, to excel in artistic and crafts activities, and can interfere with learning a musical instrument or mastering a computer keyboard. The term **dyspraxia** relates to difficulty in developing an ideomotor plan and activating coordinated and integrated visual motor actions to complete a task or solve a motor problem, such as assembling a model.

Some children exhibit **gross motor incoordination.** They have problems in processing "outer spatial" information to guide gross motor actions. Affected children may be inept at catching or throwing a ball because they cannot form accurate judgments about trajectories in space. Others demonstrate diminished body position sense. They do not efficiently receive or interpret proprioceptive and kinesthetic feedback from peripheral joints and muscles. They are likely to evidence difficulties when activities demand balance and ongoing tracking of body movement. Others are unable to satisfy the motor praxis demands of certain gross motor activities. It may be hard for them to recall or plan complex motor procedures such as those needed for dancing, gymnastics, or swimming. Children with gross motor problems can incur considerable embarrassment in physical education classes. Gross motor weaknesses can lead to social rejection, withdrawal, and generalized feelings of inadequacy.

Language

Language is one of the most critical and complex cognitive functions and can be broadly divided into r**eceptive** (auditory comprehension/understanding) and e**xpressive** (speech and language production and/or communication) functions. Children who primarily experience receptive language problems may have difficulty understanding verbal information, following instructions and explanations, and interpreting what they hear. Expressive language weaknesses can result from problems with speech production and/or problems with higher level language development (see Chapter 35). Speech production difficulties include oromotor problems affecting articulation, verbal fluency, and naming. Some children have trouble with sound sequencing within words. Others find it hard to regulate the rhythm or prosody of their verbal output. Their speech may be dysfluent, hesitant, and inappropriate in tone. Problems with word retrieval can result in problems in finding exact words when needed (as in a class discussion) or substituting definitions for words (circumlocution). Children who evidence higher level expressive language impediments have trouble formulating sentences, using grammar acceptably, and organizing spoken (and possibly written) narratives.

In considering disordered language, whether in reception or expression, it is vital to ascertain the potential underlying difficulties that are contributing. Some children, for example, have particular problems with **phonology** (see Chapter 35). Commonly, a weak phonologic sense has a negative effect not only on language processing, but also on the development of reading, writing and even mathematics (e.g., word problems). Children with **semantic deficits** have trouble learning the meaning of words, and as a result, may use words improperly (e.g., out of context). Other common language deficiencies include difficulty with **syntax** (word order), problems with **discourse** (paragraphs and passages), an underdeveloped sense of **metalinguistics** (the ability to think about and analyze how language works), and trouble with drawing appropriate inferences (supplying missing information) from language. Difficulty with language **pragmatics**, or the social understanding and application of language, can be another significant impediment.

Language weaknesses not only contribute to problems with reading, writing and math, but can also manifest in the content areas, such as the sciences, which necessitate the processing of dense verbal material in textbooks and the rapid convergent recall of facts, and social studies courses that often entail the use of sophisticated language and verbal abstract concepts (e.g., democracy). Learning foreign languages can be a serious problem. In contrast, children who possess strong language skills are often able to make use of their linguistic facility to compensate for any academic problems; it may be possible to verbalize one's way through a mathematics curriculum, thereby circumventing a tendency to be confused by predominantly nonverbal concepts (e.g., ratio, equation, and diameter).

To one degree or another, all academic skills are taught largely through language, and thus it is not surprising that children who experience language dysfunction often experience problems with academic performance. In fact, some studies suggest that up to 80% of children who present with a SLD also experience language-based weaknesses.

Visual–Spatial/Visual–Perceptual Function

The process of visual development begins well before birth, with continued development and refinement throughout childhood (see Chapter 621). Important structures involved in the development and function of the visual system, beyond the eyes themselves, include the retina, optic cells (e.g., rods and cones), the optic chiasm, the optic nerves, the brainstem (control of automatic responses like pupil dilation), the thalamus (e.g., lateral geniculate nucleus for form, motion, color), and the primary (visual space and orientation) and secondary (color perception) visual processing regions located in and around the occipital lobe. Other brain areas, considered to be outside of the primary visual system, are also important to visual function, helping to process *what* (temporal lobe) is seen and *where* it is located in space (parietal lobe). The left and right cerebral hemispheres interact considerably in visual processes, with each hemisphere possessing more specialized functions, including left hemisphere mediated processing of details, patterns, and linear information, and right hemisphere processing of the gestalt and overall form.

Some of the more critical aspects of visual processing to develop in the school-age child include **spatial relations**—the ability to accurately perceive objects in space in relation to other objects; **visual**

discrimination—the ability to differentiate and identify objects based on their individual attributes such as size, shape, color, form, and position; and, **visual closure—**the ability to recognize or identify an object even when the entire object cannot be seen.

Children with subtle visual deficits are often misidentified and/or missed completely. Indications of visual processing deficits in the school-age child may include difficulty learning to draw and write, and problems with art activities. These children might also have trouble discriminating between left and right. They might encounter problems recognizing letters and words, resulting in delayed reading, spelling, and writing.

Visual–spatial processing dysfunctions are not a common cause of chronic reading disorders, but more recent investigations have established that deficits in orthographic coding (visual–spatial analysis of character-based systems) can contribute to reading disorders. Spelling and writing can emerge as a weakness because children with visual processing problems commonly have trouble with the precise visual configurations of words. In mathematics, these children often have difficulty with visual–spatial orientation, with resultant difficulty aligning digits in columns when performing calculations and/or difficulty managing geometric material. In the social realm, intact visual processing allows a child to make use of visual or physical cues when communicating and interpreting the paralinguistic aspects of language. Secure visual functions are also necessary to process proprioceptive and kinesthetic feedback and to coordinate movements during physical activities. Children with visual processing deficits are thus susceptible to problems such as social isolation and withdrawal and consequent behavioral and/or emotional difficulties.

Intellectual Function

The concept of intellectual function, or intelligence, has had many definitions and theoretical models, and achieving a consensus on the subject has been challenging. Well-known theories include Spearman's unitary concept of "the g-factor," the "verbal and nonverbal" theories (e.g., Binet, Thorndike), the 2-factor theory from Catell (crystallized vs fluid intelligence), Luria's simultaneous and successive processing model, and more recent models that view intelligence as a global construct composed of more-specific cognitive functions (e.g., auditory and visual–perceptual processing, spatial abilities, processing speed, and working memory). A useful definition of **intellectual function** is the capacity to think in the abstract, reason, problem solve and comprehend.

The expression of intellect is mediated by many factors, including language development, sensorimotor abilities, genetics, heredity, environment, and neurodevelopmental dysfunction or neuropathology. When an individual's intelligence is measured at a standard score of 70 or lower, and significant weaknesses in adaptive skills are indicated, consideration of the diagnosis of Intellectual Disability would be warranted. In DSM-5, the previous diagnostic term of Mental Retardation has been changed to **Intellectual Disability**. DSM-5 also includes the term **Intellectual Developmental Disorder** to indicate weaknesses in intellectual functioning that begin during the early developmental period (Chapter 36).

The clinical assessment of intellectual functioning has proved useful in identifying intellectual disability, informing treatment strategies, and in predicting future functionality (e.g., academic, occupational and social). Notwithstanding, intelligence test scores (e.g., IQ) reflect only part of an individual's ability profile. Functionally, there are some common characteristics that distinguish children with deficient intellectual functioning from those with average or above average abilities. Typically, those at the lowest end of the spectrum (e.g., profound or severe intellectual deficiencies) are incapable of independent function, and require a highly structured environment with constant aid and supervision (see Chapter 36). At the other end of the spectrum are those with unusually well-developed intellect (e.g., gifted). Although this level of intellectual functioning offers many opportunities, it can also be associated with functional challenges related to socialization, learning style, and communication and perceptual differences. Individuals whose intellect falls in the below average range (sometimes referred to as the "borderline" or "*slow learner" range*) tend to experience greater difficulty processing and managing information that is abstract, making connections between concepts and ideas, and generalizing information (e.g., may be able to comprehend a concept in one setting but are unable to carry it over and apply it in different situation). In general, these individuals tend to do better when information is presented in more concrete and explicit terms, and when working with rote information (e.g., memorizing specific material). Stronger intellect is associated with better-developed concept formation, critical thinking, problem solving, understanding and formulation of rules, brainstorming and creativity, and metacognition (the ability to "think about thinking")

Frontal Lobe Functioning

Attention

Most brain processes are heavily dependent on functional arousal, alertness, and attention. Any malfunction within or across these systems will likely cause some degree of breakdown in other cognitive processes. Functional attention subsumes intact neuroanatomic and neurochemical brain systems. Structurally, brain regions involved include subcortical, cortical, and association areas throughout the brain. Primary structures involved include brainstem regions (e.g., basal ganglia), the limbic system (e.g., amygdala and hippocampus), and the frontal lobes (e.g., prefrontal cortex). The neurotransmitter dopamine, along with its neuronal pathways, has been identified as a major chemical modulator of attention. It is through the cognitive mechanisms of attention and executive functions that the child's brain acquires, organizes, and processes information. These mechanisms also allow the child to regulate, plan, and monitor their behaviors and thoughts. Children with attention dysfunction comprise a widely heterogeneous group who show various patterns of impairment of these systems (see Chapter 33). The resulting symptoms not only affect behavior, learning, and academic skills development, but also have an impact on the child's emotional, social, and adaptive development and functioning.

Attention is far from a unitary, independent, or specific function. This may be illustrated best through the phenotype associated with **Attention-Deficit/Hyperactivity Disorder (ADHD).** ADHD is not only a disorder of impaired focus, but also includes a host of symptoms related to problems with vigilance, distractibility, impulsivity in thought and behavior, hyperactivity, and flexibility. Disordered attention can occur owing to faulty mechanisms in and/or across subdomains of attention. These subdomains include **selective attention** (the ability to focus attention to a particular stimulus and to discriminate relevant from irrelevant information), **divided attention** (the ability to orient to more than one stimulus at a given time), **sustained attention** (the ability to maintain one's focus), and **alternating attention** (the capacity to shift focus between stimuli).

Attention problems in school-age children can manifest at any point in the process, from arousal through output. Children with diminished alertness and arousal can exhibit signs of mental fatigue in a classroom or when engaged in any activity requiring sustained focus. They might yawn, stretch, fidget, and daydream. They can become overactive in an effort to attain or maintain a higher level of arousal. They are apt to have difficulty allocating and sustaining their concentration, and their efforts may be erratic and unpredictable, with extreme performance inconsistency. These children can also have difficulty discriminating between important and unimportant information. Such weaknesses of determining saliency often result in focusing on the wrong stimuli, at home, in school, and socially, and can result in the child's missing important information and can impede their ability to take notes, to summarize information, or to recognize what to study for a test. In the social context, poor attention may result in inept social interaction (e.g., because of factors such as not "hearing" what others say). Some children present with what has been termed *sluggish cognitive tempo*. Children with sluggish cognitive tempo have many inattentive features without a history of significant hyperactivity and/or impulsiveness. Some researchers believe that sluggish cognitive tempo may be a different disorder from ADHD, with its own characteristics, including hypoactivity, lethargy, confusion, and mental "fogginess."

Distractibility can take the form of listening to extraneous noises instead of a teacher, staring out the window, or constantly thinking about the future. These children often show evidence of superficial concentration, where their level of focus is not of sufficient intensity to capture specific information. As a result, these children are often described as "forgetful" because directions and explanations need to be repeated and details (e.g., changes in operational signs in mathematics) may be missed. These children can also exhibit difficulties with cognitive activation and generalization, passively processing and not linking information with prior knowledge and experience, or overrelying on prior experience.

Attention dysfunction can affect the output of work, behavior, and/or social activity. These children have a tendency to perform or act without previewing a likely outcome or thinking through the potential consequences of what they are about to do or say. Their impulsivity can lead to careless mistakes in academic work and unintended misbehavior. It is important to appreciate that most children with attentional dysfunction also harbor other forms of neurodevelopmental dysfunction that can be associated with academic disorders (with some estimates suggesting up to 60% comorbidity).

Executive Functioning

There is considerable overlap between attention and **executive functioning**. Additions to the ICD classification system include a code for *Frontal Lobe and Executive Function Deficit* (799.55). Executive functioning is an umbrella term used to describe specific cognitive processes involved in regulating, guiding, organizing, and monitoring of thoughts and actions (cognitive, behavioral, and emotional functions) to achieve a specific goal. Processes considered to be executive in nature include inhibition control, flexibility (the ability to shift between activities or thoughts), emotional control, initiation skills, planning, organization, working memory, and self-monitoring.

Studies indicate that executive functioning can be strengthened in children as young as age 4 yr, which suggests that executive functioning is actively developing in the preschool-age child.

Executive function deficits that have particular impact on school function include **inhibition**, or **inhibitory control**, the ability to control a response, whether it be cognitive or behavioral. Children with inhibitory control deficits may answers questions prematurely and fail to check their work. Behaviorally, these children may speak without first considering the impact of what they say. In the social context, disinhibited children may interrupt others and demonstrate other impulsive behaviors that often interfere with interpersonal relationships (see Chapter 33).

The function of **working memory** has been the focus of significant research efforts. Working memory can be defined as the ability to hold, manipulate, and store information for short periods. In its simplest form, working memory involves the interaction of short-term verbal and visual processes (e.g., memory, phonologic, awareness and spatial skills) with a centralized control mechanism that is responsible for coordinating all of the cognitive processes involved (e.g., temporarily suspending information in memory while working with it). Developmentally, working memory capacity can double or triple between the preschool years and adolescence. A child with working memory dysfunction might carry a number and then forget what it was that the child intended to do after carrying that number. Working memory is an equally important underlying function for reading, where it enables the child to remember the beginning of a paragraph when the child arrives at the end of it. In writing, working memory helps children remember what they intend to express in written form while they are performing another task, like placing a comma or working on spelling a word correctly. Working memory also enables the linkage between new incoming information in short-term memory with prior knowledge or skills held in longer-term memory (Table 32-1).

Table 32-1 Symptom Expression of Executive Dysfunction

EXECUTIVE FUNCTION DEFICIT	SYMPTOM EXPRESSION
Disinhibition	Impulsivity/poor behavioral regulation Interrupts "Blurts" things out
Shifting	Problems with transitioning from one task/activity to another Unable to adjust to unexpected change Repeats unsuccessful problem-solving approaches
Initiation	Difficulty independently beginning tasks/activities Lacks initiative Difficulty developing ideas or making decisions
Working memory	Challenges following multistep instruction (e.g., only completes 1 of 3 steps) Forgetfulness
Organization and planning	Fails to plan ahead Work is often disorganized Procrastinates and does not complete tasks "Messy" child
Self-monitoring	Fails to recognize errors and check work Does not appreciate impact of actions on others Poor self-awareness
Affect control	Experiences behavioral and emotional outbursts (e.g., tantrums) Easily upset/frustrated Frequent mod changes

Memory

Memory is a term used to describe the cognitive mechanism by which information is acquired, retained, and recalled. Structurally, some major brain areas involved in memory processing include the hippocampus, the fornix, the temporal lobes, and the cerebellum, with connections in and between most brain regions. The memory system can be partitioned into subsystems based on processing sequences; the form, time span, and method of recall; whether memories are consciously or unconsciously recalled; and the types of memory impairments that can occur.

Once information has been identified (through auditory, visual, tactile, and/or other sensory processes), it needs to be **encoded and registered,** a mental process that constructs a representation of the information into the memory system. The period of time (typically seconds) during which this information is being held and/or manipulated for registration, and ultimately encoded, consolidated, and retained, is referred to as **working memory** (see above). Other descriptors include **short-term memory** and **immediate memory**. **Consolidation** and **storage** represent the process by which information in short-term memory is transferred into **long-term memory**. Information in long-term memory can be available for hours or as long as a life span. Long-term memories are generally thought to be housed, in whole or in part, in specific brain regions (e.g., the cortex, cerebellum). Ordinarily, consolidation in long-term memory is accomplished in 1 or more of 4 ways: pairing 2 bits of information (such as a group of letters and the English sound it represents); storing procedures (consolidating new skills, such as the steps in solving mathematics problems); classifying data in categories (filing all insects together in memory); and linking new information to established rules, patterns, or systems of organization (rule-based learning).

Once information finds its way into long-term memory, it must be accessed. In general, information can be retrieved spontaneously (a process known as **free recall**) or with the aid of cues (**cued or recognition recall**). Some other common descriptors of memory include **anterograde memory** (the capacity to learn from a single point in time

forward), **retrograde memory** (the capacity to recall information that was already learned), and **explicit memory** (conscious awareness of recall), **implicit memory** (subconscious recall: no awareness that the memory system is being activated), **procedural memory** (memory for how to do things), and **prospective memory** or *remembering to remember*.

As children proceed through school, the demands for the efficient use of memory progressively increase. By secondary school, rapid and precise recall is heavily emphasized. Children can have trouble with 1 or more memory mechanisms. They might struggle with the initial registration of information in short-term memory. Others might have difficulty storing newly introduced information. Other children might have difficulty accessing (retrieving) information, despite having registered and stored it effectively. Children can experience frustration in their efforts at consolidating information into long-term memory and/or encounter difficulty with simultaneous recall (retrieval of several facts or procedures at once). Some students exhibit delayed **automatization:** not enough of what they have learned in the past is accessible to them instantaneously and with no expenditure of effort. Such skills as forming letters, mastering mathematical facts, and decoding words must ultimately become automatic if students are to make good academic progress.

Weaknesses with memory processing can be highly specific and/or dependent on the material. Some children struggle to learn visual-spatial material, whereas others may be deficient in learning auditory information. Some have difficulty processing linear data or sequential information. Some can experience difficulty with rote data (e.g., word lists) yet have little or no difficulty registering information in context (e.g., a narrative). Although in-depth examination (e.g., neuropsychologic testing) is often necessary to differentiate potential memory weaknesses and their impact on the child's overall functioning, screening for memory problems should be part of any well-child examination.

Social Cognition

For the school-age child, the development and effective use of social skills is of immeasurable importance. It is heavily dependent on secure **social cognition**, which is composed of mental processes that allow an individual to understand and interact with the social environment. Although some evidence shows that social cognition exists as a discrete area of neurodevelopmental function, multiple cognitive processes are involved with social cognition. These include the ability to recognize, interpret, and make sense of the thoughts, communications (verbal and nonverbal), and actions of others, the ability to understand that others' perceptions, perspectives, and intentions might differ from our own (commonly referred to as "theory of mind"), the ability to use language to communicate with others socially (pragmatic language), and the ability to make inferences about others and/or the environment based on contextual information. It can also be argued that social cognition involves processes associated with memory and executive functions like flexibility.

CLINICAL MANIFESTATIONS

School-age children with neurodevelopmental dysfunctions vary widely with regard to clinical presentations. Their specific patterns of academic performance and behavior represent final common pathways, the convergence of many forces, including interacting cognitive strengths and deficits; environmental, social, or cultural factors; temperament; educational experience; and intrinsic resilience (Table 32-2). Symptoms of academic disorders differ with age. Children in preschool or kindergarten might present with delayed language development, including problems with articulation, vocabulary development, word finding and rhyming. They often experience early challenges with learning colors, shapes, letters and numbers, the alphabet, and days of the week. Difficulty following instructions, overactivity, and distractibility may be early symptoms of emerging attention and inhibitory control weaknesses. Difficulties with fine motor development (e.g., grasping crayons and pencils, coloring or drawing) and social interaction are not uncommon. As these children enter elementary school, they can evidence problems integrating and associating letters and sounds and problems with semantic knowledge such as mixing up their words (like go and eat). While learning to read and spell, challenges with reversals (b/d), inversions (m/w), transpositions (felt/left), and substitutions (house/home) might persist. Reading comprehension may be weak.

Table 32-2 Neurodevelopmental Dysfunction Underlying Academic Disorders

ACADEMIC DISORDER	POTENTIAL UNDERLYING NEURODEVELOPMENTAL DYSFUNCTION
Reading	Language • Phonologic processing • Verbal fluency • Syntactic and semantic skills Memory • Working memory Sequencing Visual–spatial Attention
Written expression, spelling	Language • Phonologic processing • Syntactic and semantic skills Graphomotor Visual–spatial Memory • Working memory Sequencing Attention
Mathematics	Visual–spatial Memory • Working memory Language Sequencing Graphomotor Attention

Isolated neurodevelopmental dysfunction can lead to a specific academic disorder, but more often there is a combination of factors underlying weak academic performance. In addition to the dysfunction in neurodevelopmental domains as listed in the table, the clinician must also consider the possibility of limitations of intellectual and cognitive abilities or associated social and emotional problems.

Children with early signs of a mathematics weakness might have difficulty with concepts of quantity or with adding or subtracting without using concrete representation (e.g., their fingers when calculating). Difficulty learning time concepts and confusion with directions (right/left) might also be observed. Sequencing problems are noted in reading, spelling and writing, and mathematics. Poor fine motor control and coordination and poor planning can lead to spelling and writing problems. Attention and behavioral regulation weaknesses observed earlier can continue, and together with executive functioning weaknesses (e.g., organization, initiation skills), further complicate the child's ability to acquire and generalize new knowledge.

Middle school brings with it a significant shift in cognitive, academic, and regulatory demands, as children in this age group are expected to be increasingly independent, causing further difficulties for a child with existing attention, inhibitory, and/or executive challenges. In reading and writing, middle school children might present with transposition and sequencing errors; might struggle with root words, prefixes, and suffixes; might have difficulty with written expression; and might avoid reading and writing altogether. Challenges completing word problems in math are common. Difficulty with recall of information might also be experienced. Although observable in both lower and more advanced grades, behavioral, emotional, and/or social difficulties tend to become more salient in middle school children who experience cognitive and/or academic problems.

Many of these challenges continue well into high school. High school students can present with deficient reading comprehension, written expression, and slower processing efficiency. Trouble answering

open-ended questions, dealing with abstract information, and producing executive control (e.g., self-monitoring, organization, planning, and self-starting) is often reported.

Reading

Reading disorders (see Chapter 34), also termed **dyslexia,** can stem from any number of neurodevelopmental dysfunctions as described earlier (see Table 32-2). Most commonly, language and/or auditory processing weaknesses are present as evidenced by poor **phonologic processing.** Challenges with phonologic processing often result in deficiencies at the level of decoding individual words and, consequently, a delay in automaticity (e.g., acquiring a repertoire of words they can identify instantly) that causes reading to be slow, laborious, and frustrating. Without effective identification and intervention, reading comprehension, and ultimately the acquisition of knowledge may be seriously compromised. Deficits in other core neurodevelopmental domains might also be present. Weak working memory might make it difficult for a child to hold sounds and/or symbols in mind while breaking down words into their component sounds or might cause reading comprehension problems. Some children experience temporal-ordering weaknesses and struggle with reblending phonemes into correct sequences. Memory dysfunction can cause problems with recall and summarization of what was read. Some children with higher-order cognitive deficiencies have trouble understanding what they read because they lack a strong grasp of the concepts in a text. Although relatively rare as a cause of reading difficulty, problems with visual–spatial functions (e.g., visual perception) can cause children difficulty in recognizing letters. It is not unusual for children with reading problems to avoid reading practice, and a delay in reading proficiency becomes increasingly pronounced and difficult to remediate.

Spelling and Writing

Spelling and writing impairments share many related underlying processing deficits with reading, so it is not surprising that the 2 disorders often occur simultaneously in school-age children (see Table 32-2). Core neurodevelopmental weaknesses can include phonologic and decoding difficulties, **orthographic** problems (coding letters and words into memory), and **morphologic** deficits (use of suffixes, prefixes, and root words). Problems in these areas can manifest as phonetically poor, yet visually comparable approximations to the actual word (*faght* for *fight*), spelling that is phonetically correct but visually incorrect (*fite* for *fight*), and inadequate spelling patterns (*played* as *plade).* Children with memory disorders might misspell words because of coding weaknesses. Others misspell because of poor auditory working memory that interferes with their ability to process letters. Sequencing weaknesses often result in transposition errors when spelling. Overall, the careful analysis of a child's errors can provide valuable insights into the nature of their spelling problems. As children proceed through school, demands increase for large amounts of well-organized written output.

Writing difficulties have been classified as **disorder of written expression**, or **dysgraphia** (see Table 32-2). Although many of the same dysfunctions described for reading and spelling can contribute to problems with writing, written expression is the most complex of the language arts, requiring synthesis of many neurodevelopmental functions (e.g., auditory, visual–spatial, memory, executive). Deficits in any of these domains can be problematic. Even when a child's phonologic and/or orthographic skills are functional, the child can experience writing problems owing to weaknesses with language, attention, sequencing and/or fine motor development. These weaknesses can occur in written output that is difficult to comprehend, disjointed, and/or poorly organized. The child with working memory challenges can lose track of what the child intended to write. Attention deficits can make it hard for a child to mobilize and sustain the mental effort, pacing, and self-monitoring demands necessary for writing. In many cases, writing is laborious because of an underlying graphomotor dysfunction (e.g., fluency does not keep pace with ideation and language production). Thoughts may also be forgotten or underdeveloped during writing because the mechanical effort is so taxing.

Mathematics

Delays in mathematical ability, known as **mathematics disorder** or **dyscalculia,** can be especially refractory to correction, partly because math involves the assimilation of both procedural knowledge (e.g., calculations) and higher-order cognitive processes (e.g., working memory) (see Table 32-2). A school-based study found that no student who was delayed for longer than 6 mo in mathematics in 6th grade ever caught up; another study found persistence of severe arithmetic disorder in half of affected preteen children. Factors associated with persistence of difficulties included the disorder's severity and heritability. Significant mathematical weaknesses can become virtually insurmountable because the subject is so cumulative in its structure.

Some children experience mathematics failure because of weaknesses in reasoning and problem solving (e.g., intellectual functioning). It may be hard for them to grasp and apply concepts effectively and/or systematically. Good mathematicians are able to use both verbal and perceptual conceptualization to understand such concepts as fractions, percentages, equations, and proportion. Children with language dysfunctions have difficulty in mathematics because they have trouble understanding their teachers' verbal explanations of quantitative concepts and operations and are likely to experience frustration in solving word problems and in processing the vast network of technical vocabulary in math. Mathematics also relies on visualization. Children who have difficulty forming and recalling visual imagery may be at a disadvantage in acquiring mathematical skills. They might experience problems writing numbers correctly, placing value locations, and processing geometric shapes or fractions. Children with attention, inhibitory control, or executive deficits (e.g., working memory) may be unable to focus on fine detail (such as operational signs), might take an impulsive approach to problem solving, engage in little or no self-monitoring, forget components of the same problem, or commit careless errors. When a child's memory system is weak, the child might have difficulty recalling appropriate procedures and automatizing mathematical facts (e.g., multiplication tables). Moreover, it is not unusual for children with mathematical disabilities to have superimposed mathematics phobias. Anxiety over mathematics can be especially debilitating.

Nonacademic Problems

Neurodevelopmental dysfunctions commonly have effects that extend far beyond academic performance. These effects may be related to the dysfunctions themselves or to secondary sequelae (e.g., persistent failure and frustration). The impulsivity and lack of effective self-monitoring of children with attention and impulse-control deficits can lead to unacceptable actions that were unintentional. Children with neurodevelopmental dysfunctions can experience excessive performance anxiety or clinical depression, and sadness, self-deprecatory comments, declining self-esteem, chronic fatigue, loss of interests, and even suicidal ideation can ensue. Some children lose motivation. They tend to give up and exhibit learned helplessness, a sense that they have no control over their destiny. Therefore, they feel no need to exert effort and develop future goals. These children may be easily led toward dysfunctional interpersonal relationships, detrimental behaviors (e.g., delinquency), and the development of mental health and personality disorders, such as mood disorders (see Chapter 26) or antisocial personality disorder.

ASSESSMENT AND DIAGNOSIS

The primary care pediatrician has a critical role in identifying and evaluating the child with an academic disorder. A system of screening and surveillance should be incorporated into routine office visits to promote early identification of academic difficulties. The pediatrician should be aware of a family medical history that includes a parent who still struggles with reading or time management, or an older sibling who has failed at school. Factors in the child's medical history should be flagged, such as extreme prematurity or chronic medical conditions. Children with low birthweight and those born prematurely who appear to have been spared more serious neurologic problems might only manifest academic problems later in their school career and they

warrant particular attention. Children falling into these high risk categories should be flagged for an increased level of scrutiny at routine well-child visits as well as acute-care visits, especially if physical complaints are nonspecific. There should be a low threshold for initiating further school performance screening and assessment of these children. Warning signs might be subtle or absent and problems will not be recognized unless there is a system of eliciting and identifying school problems as part of the routine well-child visit. Parents might have concerns about their child's learning progress but be reluctant to share these with the pediatrician unless prompted such as through completion of a standard developmental screening questionnaires or direct questioning of parents regarding possible concerns about their child's school performance. Inconsistency in report from grade to grade may sometimes be caused by a difference in teaching styles or classroom demands. The type of deficit will also be influential; for example, problems with basic phonemic awareness would be more apparent earlier, while reading comprehension difficulties would emerge later.

Review of school report cards can provide useful clues to patterns of neurodevelopmental dysfunction. In addition to the patterns of grades in the various academic skill areas, it is also important to review ratings of classroom behavior, sometimes listed under headings such as deportment, behavior, conduct, effort/work habits, or citizenship. Review of standardized testing is helpful, and poor scores could be caused by a learning disorder, ADHD, anxiety, lack of motivation, or some combination thereof. Conversely, above-average scores tend to rule out learning or attention problems, but motivation or adjustment issues could then explain a discrepancy between standardized scores and classroom performance. Comparison of how long the homework should take, and how long it takes the child is recommended. Children with ADHD, learning disorders, or emotional/behavioral issues often find homework to be a contentious activity.

The primary care physician is responsible for identifying or ruling out any underlying or associated medical problems that could be impeding the academic performance of the patient who is struggling in school. Vision and hearing screening are critical components of the medical evaluation and any suspicion of sensory difficulty should warrant referral for more definitive testing. The influence of chronic medical problems or potential side effects of medications should be considered. Sleep deprivation is increasingly being recognized as a contributor to academic problems and the possibility of substance abuse must always be a consideration, especially in the adolescent who was previously achieving well at school and has manifested a rapid decline in academic performance.

The physician should be alert for dysmorphic physical features, minor congenital anomalies, or constellations of physical findings (such as cardiac anomalies and palatal anomalies in velocardiofacial syndrome) and should perform a detailed neurologic examination. Special investigations, such as electroencephalograms or brain scans, are not indicated in the absence of specific medical findings. Measures of brain function, such as functional MRI, offer insight into possible areas of neurodevelopmental dysfunction, but they largely remain only research tools with limited application in the general clinical setting at this time.

If problems emerge, the pediatrician should address medical causes or associated conditions. The pediatrician can advise and assist parents in obtaining necessary psychoeducational and/or emotional evaluations through the school or by referral to independent clinicians.

Those physicians with a particular interest in learning disorders can extend their participation in the evaluation process. They can obtain data on neurodevelopmental function through the use of questionnaires completed by the parents, the school, and (if old enough) the child, providing information about behavioral adjustment, patterns of academic performance, and traits associated with specific developmental dysfunctions. Screening instruments such as the Pediatric Symptoms Checklist and standardized behavioral questionnaires, including the Child Behavior Checklist (CBCL) and the Behavior Assessment System for Children–Second Edition (BASC-2) can aid in evaluation (see Chapter 20).

The physician may also perform an extended neurologic and developmental assessment. Available pediatric neurodevelopmental examination instruments that facilitate direct sampling of various neurodevelopmental functions, such as attention, memory, and language, include the Pediatric Early Elementary Examination (PEEX II) and the Pediatric Examination of Educational Readiness at Middle Childhood (PEERAMID II). Examinations of this type also include direct behavioral observations and assessment of minor neurologic indicators (sometimes called *soft signs*). The latter include various associated movements and other phenomena often associated with neurodevelopmental dysfunction.

A child who is functioning poorly during the school years usually requires a *multidisciplinary evaluation*, including a pediatrician, a psychologist, and, if possible, a psychoeducational specialist (sometimes called an *educational diagnostician*) who can undertake a detailed analysis of academic skills and subskills. Other professionals should become involved, as needed, in individual cases, such as a speech-language pathologist, an occupational therapist, a neurologist, and a social worker. In some cases, more in-depth examination of a child's neurocognitive status is warranted. This is particularly true for children who present with developmental or cognitive difficulties in the presence of a medical condition (e.g., epilepsy, traumatic brain injury, childhood cancers/brain tumors, genetic conditions). A neuropsychologic evaluation involves comprehensive assessment of brain function as a means of understanding brain function across domains. The goal of neuropsychologic assessment is to understand brain function via identification of a child's profile of cognitive strengths and weaknesses. Neuropsychologic data are often analyzed together with other tests (e.g., structural), such as MRIs, to look for supporting evidence of any areas of difficulty (e.g., memory weaknesses associated with temporal lobe anomalies).

Many children undergo evaluations in school. Such assessments are guaranteed in the United States under Public Law 101-476, the IDEA. In addition, children found to have attentional dysfunction and other disorders might qualify for educational accommodations under Section 504 of the Rehabilitation Act of 1973.

Multidisciplinary evaluations conducted in schools are usually very helpful, but they are focused primarily on determining whether a student meets the eligibility criteria for special education services. School budgeting constraints or lack of personnel can also affect the quality of evaluations and the extent of recommended services. Many parents seek independent evaluations or second opinions outside of the school setting, and pediatricians can facilitate such outside assessments.

Psychoeducational testing can yield relevant data, especially when such assessments include careful analyses that pinpoint where breakdowns are occurring in the processes of reading, spelling, writing, and mathematics. Input from multiple sources can be used in formulating specific recommendations for regular and special educational teachers and for interventions that can be implemented at home. A mental health specialist can be valuable in identifying family-based issues or psychiatric disorders that may be complicating or aggravating neurodevelopmental dysfunctions.

TREATMENT

There are a number of standard approaches that should be incorporated into any management plan for a student who is struggling academically. The primary physician can play an important role as a consultant in overseeing and monitoring the implementation of these steps. Management of children with neurodevelopmental dysfunctions often needs to be multidisciplinary. Most children require several of the following forms of intervention.

Demystification

Many children with neurodevelopmental dysfunctions have little or no understanding of the nature or sources of their academic difficulties. Once an appropriate descriptive assessment has been performed, it is important to explain to the child the nature of the dysfunction while delineating the child's strengths. This explanation should be provided

in nontechnical language, communicating a sense of optimism and a desire to be helpful and supportive.

Bypass Strategies (Accommodations)

Numerous techniques can enable a child to circumvent neurodevelopmental dysfunctions. Such bypass strategies are ordinarily used in the regular classroom. Examples of bypass strategies include using a calculator while solving mathematical problems, writing essays with a word processor, presenting oral instead of written reports, solving fewer mathematical problems, being seated near the teacher to minimize distraction, presenting correctly solved mathematical problems visually, and taking standardized tests untimed. These bypass strategies do not cure neurodevelopmental dysfunctions, but they minimize their academic and nonacademic effects and can provide a scaffold for more successful academic achievement.

Interventions (Remediation of Skills)

Interventions can be implemented at home and in school to strengthen the weak links in academic skills. Reading specialists, mathematics tutors, and other such professionals can use diagnostic data to select techniques that use a student's neurodevelopmental strengths in an effort to improve decoding skills, writing ability, or mathematical computation skills. Remediation need not focus exclusively on specific academic areas. Many students need assistance in acquiring study skills, cognitive strategies, and productive organizational habits.

Early identification is critical so that appropriate instructional interventions can be introduced in an effort to minimize the long-term effects of academic disorders. Any interventions should be empirically supported (e.g., phonologically based reading intervention has been shown to significantly improve reading skills in school-age children). Remediation may take place in a resource room or learning center at school and is usually limited to children who have met the educational criteria for special education resource services as described earlier.

Interventions that can be implemented at home could include drills to aid the automatization of subskills, such as arithmetic facts or letter formations, or the use of phonologically based reading programs.

There are a number of treatment/intervention approaches to strengthening executive function that have demonstrated positive findings. These include computerized training programs such as CogMed (Pearson) that has been demonstrated to strengthen working memory skills in children via a computer game model. Curriculum-based classroom programs, such as the Tools of the Mind (Tools) and PATHS (Promoting Alternative Thinking Strategies) also have accumulating research support. These programs employ approaches such as social play and target areas such as self-control and problem-solving to teach and strengthen executive functions. Aerobic exercise and martial arts such as Tae Kwon Do, which stresses discipline and emphasizes the development of self-regulation (e.g., impulse control), have demonstrated improvements that generalize in many aspects of executive functions and attention.

Developmental Therapy

Controversy exists about the efficacy of treatments to enhance weak developmental functions. Nevertheless, some forms of developmental therapy are widely accepted. Speech-language pathologists commonly offer intervention for children with various forms of language disability. Occupational therapists strive to improve the motor skills of certain students with writing problems, and physical therapists address gross motor clumsiness.

Curriculum Modifications

Many children with neurodevelopmental dysfunctions require alterations in the school curriculum to succeed, especially as they progress through secondary school. Students with memory weaknesses might need to have their courses selected for them so that they do not have an inordinate cumulative memory load in any single semester. The timing of foreign language learning, the selection of a mathematics curriculum, and the choice of science courses are critical issues for many of these struggling adolescents.

Strengthening of Strengths

Affected children need to have their affinities, potentials, and talents identified clearly and exploited widely. It is as important to augment strengths as it is to attempt to remedy deficiencies. Athletic skills, artistic inclinations, creative talents, and mechanical abilities are among the potential assets of certain students who are underachieving academically. Parents and school personnel need to create opportunities for such students to build on these assets and to achieve respect and praise for their efforts. These well-developed personal assets can ultimately have implications for the transition into young adulthood, including career or college selection.

Individual and Family Counseling

When academic difficulties are complicated by family problems or identifiable psychiatric disorders, psychotherapy may be indicated. Clinical psychologists or child psychiatrists may offer long- or short-term therapy. Such intervention may involve the child alone or the entire family. Cognitive-behavioral therapy is a technique that is increasingly popular. It is essential that the therapist have a firm understanding of the nature of a child's neurodevelopmental dysfunctions.

Controversial Therapies

A variety of treatment methods for neurodevelopmental dysfunctions have been proposed that currently have no known scientific evidence base of efficacy. This list includes dietary interventions (vitamins, elimination of food additives or potential allergens), neuromotor programs or medications to address vestibular dysfunction, eye exercises, filters, tinted lenses, and various technologic devices. Parents should be cautioned against expending the excessive amounts of time and financial resources usually demanded by these remedies. In many cases, it is difficult to distinguish the nonspecific beneficial effects of increased support and attention paid to the child from the supposed target effects of the intervention.

Medication

Psychopharmacologic agents may be especially helpful in lessening the toll of neurodevelopmental dysfunctions. Most commonly, stimulant medications are used in the treatment of children with attention deficits. Although most children with attention deficits have other associated dysfunctions (such as language disorders, memory problems, motor weaknesses, or social skill deficits), medications such as methylphenidate, dextroamphetamine, lisdexamfetamine, mixed amphetamine salts, and atomoxetine can be important adjuncts to treatment by helping some children focus more selectively and control their impulsivity. When depression or excessive anxiety is a significant component of the clinical picture, antidepressants or antianxiety drugs may be helpful. Other drugs may improve behavioral control (see Chapter 21). Children receiving medication need regular follow-up visits that include a history to check for side effects, a review of current behavioral checklists, a complete physical examination, and appropriate modifications of the medication dose. Periodic trials off medication are recommended to establish whether the medication is still necessary.

Chapter 33

Attention-Deficit/ Hyperactivity Disorder

David K. Urion

Attention-deficit/hyperactivity disorder (ADHD) is the most common neurobehavioral disorder of childhood and one of among the most prevalent chronic health conditions affecting school-age children. ADHD is characterized by inattention, including increased distractibility and difficulty sustaining attention; poor impulse control and decreased self-inhibitory capacity; and motor overactivity and motor restlessness (Table 33-1). Definitions vary in different countries (Table 33-2). Affected children commonly experience academic underachievement, problems with interpersonal relationships with family members and peers, and low self-esteem. ADHD often co-occurs with other emotional, behavioral, language, and learning disorders (Table 33-3). For 40-50% of affected children, the disorder appears to continue with varying manifestations into adulthood, and leads to significant under- and unemployment, social dysfunction, and an increased risk of antisocial behaviors including substance abuse, difficulties maintaining relationships, and encounters with the law.

ETIOLOGY

ADHD may be a final common pathway for a variety of complex brain developmental processes. Mothers of children with ADHD are more likely to experience birth complications, such as toxemia, lengthy labor, and complicated delivery. Maternal drug use, smoking and alcohol use during pregnancy, lead or mercury exposure (prenatal or postnatal) are commonly linked to attentional difficulties associated with the development of ADHD. Food colorings and preservatives have inconsistently been associated with hyperactivity in previously hyperactive children.

There is a very strong genetic component to ADHD. Genetic studies have primarily implicated at least 2 candidate genes, the dopamine transporter gene *(DAT1)* and a particular form of the dopamine 4 receptor gene *(DRD4),* in the development of ADHD. Additional genes that might contribute to ADHD include *DOCK2* associated with a pericentric inversion 46N inv(3)(p14:q21) involved in cytokine regulation, a sodium-hydrogen exchange gene, other dopaminergic genes *(DRD5),* serotonergic genes *(5HTT, HTR1B),* and the synaptosomal-associated protein, SNAP-25.

Abnormal brain structures are linked to an increased risk of ADHD; 20% of children with severe traumatic brain injury are reported to have subsequent onset of substantial symptoms of impulsivity and inattention. Children with head or other injury and in whom ADHD is later diagnosed might have impaired balance or impulsive behavior as part of the ADHD, thus predisposing them to injury. Structural and functional abnormalities have been identified in children with ADHD without preexisting identifiable brain injury. These include dysregulation of the frontal subcortical circuits, small cortical volumes in this region, widespread small-volume reduction throughout the brain, and abnormalities of the cerebellum, particularly midline/vermian elements. Abnormalities in neural networks or circuits have been identified with functional MRI.

Psychosocial family stressors can also contribute to or exacerbate the symptoms of ADHD, including poverty, exposure to violence, and under- or malnutrition.

EPIDEMIOLOGY

Studies of the prevalence of ADHD across the globe have generally reported that 9% of school-age children are affected, although rates vary considerably by country, perhaps partly as a result of differing sampling and testing techniques. Rates may be higher if symptoms (inattention, impulsivity, hyperactivity) are considered in the absence of functional impairment. The prevalence rate in adolescent samples is 2-6%. Approximately 2% of adults have ADHD. ADHD is often underdiagnosed in children and adolescents. Youth with ADHD are often undertreated with respect to what is known about the needed and appropriate doses of medications. Many children with ADHD also present with comorbid neuropsychiatric diagnoses, including opposition defiant disorder, conduct disorder, learning disabilities, depression, and anxiety disorders. The incidence of ADHD appears increased in children with neurologic disorders such as epilepsies, neurofibromatosis, tuberous sclerosis (see Table 33-3).

PATHOGENESIS

MRI studies indicate that a loss of normal asymmetry in the brain, in addition to smaller brain volumes of specific structures, such as the prefrontal cortex and basal ganglia, is seen in the brains of children with ADHD. Children with ADHD have approximately a 5-10% reduction in the volume of these brain structures. Functional MRI findings suggest low blood flow to the striatum. Functional MRI data also suggest deficits in a widespread functional networks for selective and tonic attention in ADHD, that include the striatum, prefrontal regions, parietal lobe, and temporal lobe. The prefrontal cortex and basal ganglia are rich in dopamine receptors. This knowledge, plus data about the dopaminergic mechanisms of action of medication treatment for ADHD, has led to the **dopamine hypothesis,** which postulates that disturbances in the dopamine system may be related to the onset of ADHD. Fluorodopa positron emission tomography scans also support the dopamine hypothesis through the identification of low levels of dopamine activity in adults.

CLINICAL MANIFESTATIONS

Development of the *Diagnostic and Statistical Manual of Mental Disorders,* 4th edition (DSM-IV) criteria leading to the diagnosis of ADHD occurred mainly in field trials with children 5-12 yr of age. Fewer studies utilizing *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) criteria are available, but those that are available suggest a good correlation with data from DSM-IV criteria-based studies, despite the broadened age-based definition for onset of symptoms in DSM-5 (see Table 33-1). The current DSM-5 criteria state that the behavior must be developmentally inappropriate (substantially different from that of other children of the same age and developmental level), must begin before age 12 yr, must be present for at least 6 mo, must be present in 2 or more settings and reported as such by independent observers, and must not be secondary to another disorder. DSM-5 identifies 3 subtypes of ADHD. The first subtype, *ADHD, predominantly inattentive type,* often includes cognitive impairment and is more common in females. The other 2 subtypes, *ADHD, predominantly hyperactive-impulsive type,* and *ADHD, combined type,* are more commonly diagnosed in males. Clinical manifestations of ADHD may change with age. The symptoms may vary from motor restlessness and aggressive and disruptive behavior, which are common in preschool children, to disorganized, distractible, and inattentive symptoms, which are more typical in older adolescents and adults. ADHD is often difficult to diagnose in preschoolers because distractibility and inattention are may be considered developmental norms during this period.

DIAGNOSIS AND DIFFERENTIAL DIAGNOSIS

A diagnosis of ADHD is made primarily in clinical settings after a thorough evaluation, including a careful history and clinical interview to rule in or to identify other causes or contributing factors; completion of behavior rating scales by different observers from at least 2 settings (e.g., teacher and parent); a physical examination; and any necessary or indicated laboratory tests which arise from conditions suspected based on history and/or physical examination. It is important to systematically gather and evaluate information from a variety of sources, including the child, parents, teachers, physicians, and, when appropriate, other caretakers, over the course of both diagnosis and subsequent management.

Table 33-1 DSM-5 Diagnostic Criteria for Attention-Deficit/Hyperactivity Disorder

DIAGNOSTIC CRITERIA

1. A persistent pattern of inattention and/or hyperactivity-impulsivity that interferes with functioning or development, as characterized by (1) and/or (2):
   1. **Inattention:** Six (or more) of the following symptoms have persisted for at least 6 months to a degree that is inconsistent with developmental level and that negatively impacts directly on social and academic/occupational activities:
      - **Note:** The symptoms are not solely a manifestation of oppositional behavior, defiance, hostility, or failure to understand tasks or instructions. For older adolescents and adults (age 17 and older), at least five symptoms are required.
      1. Often fails to give close attention to details or makes careless mistakes in schoolwork, at work, or during other activities (e.g., overlooks or misses details, work is inaccurate).
      2. Often has difficulty sustaining attention in tasks or play activities (e.g., has difficulty remaining focused during lectures, conversations, or lengthy reading).
      3. Often does not seem to listen when spoken to directly (e.g., mind seems elsewhere, even in the absence of any obvious distraction).
      4. Often does not follow through on instructions and fails to finish schoolwork, chores, or duties in the workplace (e.g., starts tasks but quickly loses focus and is easily sidetracked).
      5. Often has difficulty organizing tasks and activities (e.g., difficulty managing sequential tasks; difficulty keeping materials and belongings in order; messy, disorganized work; has poor time management; fails to meet deadlines).
      6. Often avoids, dislikes, or is reluctant to engage in tasks that require sustained mental effort (e.g., schoolwork or homework; for older adolescents and adults, preparing reports, completing forms, reviewing lengthy papers).
      7. Often loses things necessary for tasks or activities (e.g., school materials, pencils, books, tools, wallets, keys, paperwork, eyeglasses, mobile telephones).
      8. Is often easily distracted by extraneous stimuli (for older adolescents and adults, may include unrelated thoughts).
      9. Is often forgetful in daily activities (e.g., doing chores, running errands; for older adolescents and adults, returning calls, paying bills, keeping appointments).
   2. **Hyperactivity and impulsivity:** Six (or more) of the following symptoms have persisted for at least 6 months to a degree that is inconsistent with developmental level and that negatively impacts directly on social and academic/occupational activities:
      - **Note:** The symptoms are not solely a manifestation of oppositional behavior, defiance, hostility, or a failure to understand tasks or instructions. For older adolescents and adults (age 17 and older), at least five symptoms are required.
      1. Often fidgets with or taps hands or feet or squirms in seat.
      2. Often leaves seat in situations when remaining seated is expected (e.g., leaves his or her place in the classroom, in the office or other workplace, or in other situations that require remaining in place).
      3. Often runs about or climbs in situations where it is inappropriate. (**Note:** In adolescents or adults, may be limited to feeling restless.)
      4. Often unable to play or engage in leisure activities quietly.
      5. Is often "on the go," acting as if "driven by a motor" (e.g., is unable to be or uncomfortable being still for extended time, as in restaurants, meetings; may be experienced by others as being restless or difficult to keep up with).
      6. Often talks excessively.
      7. Often blurts out an answer before a question has been completed (e.g., completes people's sentences; cannot wait for turn in conversation).
      8. Often has difficulty waiting his or her turn (e.g., while waiting in line).
      9. Often interrupts or intrudes on others (e.g., butts into conversations, games, or activities; may start using other people's things without asking or receiving permission; for adolescents and adults, may intrude into or take over what others are doing).
2. Several inattentive or hyperactive-impulsive symptoms were present prior to age 12 years.
3. Several inattentive or hyperactive-impulsive symptoms are present in two or more settings (e.g., at home, school, or work; with friends or relatives; in other activities).
4. There is clear evidence that the symptoms interfere with, or reduce the quality of, social, academic, or occupational functioning.
5. The symptoms do not occur exclusively during the course of schizophrenia or another psychotic disorder and are not better explained by another mental disorder (e.g., mood disorder, anxiety disorder, dissociative disorder, personality disorder, substance intoxication or withdrawal).

Specify whether:
- **Combined presentation:** If both Criterion A1 (inattention) and Criterion A2 (hyperactivity-impulsivity) are met for the past 6 months.
- **Predominantly inattentive presentation:** If Criterion A1 (inattention) is met but Criterion A2 (hyperactivity-impulsivity) is not met for the past 6 months.
- **Predominantly hyperactive/impulsive presentation:** If Criterion A2 (hyperactivity-impulsivity) is met and Criterion A1 (inattention) is not met for the past 6 months.

Specify if:
- **In partial remission:** When full criteria were previously met, fewer than the full criteria have been met for the past 6 months, and the symptoms still result in impairment in social, academic, or occupational functioning.

Specify current severity:
- **Mild:** Few, if any, symptoms in excess of those required to make the diagnosis are present, and symptoms result in no more than minor impairments in social or occupational functioning.
- **Moderate:** Symptoms or functional impairment between "mild" and "severe" are present.
- **Severe:** Many symptoms in excess of those required to make the diagnosis, or several symptoms that are particularly severe, are present, or the symptoms result in marked impairment in social or occupational functioning.

Clinical Interview and History

The clinical interview allows a comprehensive understanding as to whether the symptoms meet the diagnostic criteria for ADHD. During the interview, the clinician should gather information pertaining to the history of the presenting problems, the child's overall health and development, and the social and family history. The interview should emphasize factors that might affect the development or integrity of the central nervous system or reveal chronic illness, sensory impairments, or medication use that might affect the child's functioning. Disruptive social factors, such as family discord, situational stress, and abuse or neglect, can result in hyperactive or anxious behaviors. A family history of 1st-degree relatives with ADHD, mood or anxiety disorders, learning disability, antisocial disorder, or alcohol or substance abuse might indicate an increased risk of ADHD and/or comorbid conditions.

Table 33-2 Differences Between U.S. and European Criteria for ADHD or HKD

DSM-5 ADHD	ICD-10 HKD
SYMPTOMS	
Either or both of following: At least 6 of 9 inattentive symptoms At least 6 of 9 hyperactive or impulsive symptoms	All of following: At least 6 of 8 inattentive symptoms At least 3 of 5 hyperactive symptoms At least 1 of 4 impulsive symptoms
PERVASIVENESS	
Some impairment from symptoms is present in >1 setting	Criteria are met for >1 setting

ADHD, attention-deficit/hyperactivity disorder; DSM-5, *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*; HKD, hyperkinetic disorder; ICD-10, *International Classification of Diseases, 10th edition.*

Adapted from Biederman J, Faraone S: Attention-deficit hyperactivity disorder, Lancet *366:237–248, 2005.*

Table 33-3 Differential Diagnosis of Attention-Deficit/Hyperactivity Disorder

PSYCHOSOCIAL FACTORS
Response to physical or sexual abuse
Response to inappropriate parenting practices
Response to parental psychopathology
Response to acculturation
Response to inappropriate classroom setting
DIAGNOSES ASSOCIATED WITH ADHD BEHAVIORS
Fragile X syndrome
Fetal alcohol syndrome
Pervasive developmental disorders
Obsessive-compulsive disorder
Gilles de la Tourette syndrome
Attachment disorder with mixed emotions and conduct
MEDICAL AND NEUROLOGIC CONDITIONS
Thyroid disorders (including general resistance to thyroid hormone)
Heavy metal poisoning (including lead)
Adverse effects of medications
Effects of abused substances
Sensory deficits (hearing and vision)
Auditory and visual processing disorders
Neurodegenerative disorder, especially leukodystrophies
Posttraumatic head injury
Postencephalitic disorder

Note: Coexisting conditions with possible ADHD presentation include oppositional defiant disorder, anxiety disorders, conduct disorder, depressive disorders, learning disorders, and language disorders. Presence of 1 or more of the symptoms of these disorders can fall within the spectrum of normal behavior, whereas a range of these symptoms may be problematic but fall short of meeting the full criteria for the disorder.

From Reiff MI, Stein MT: Attention-deficit/hyperactivity disorder evaluation and diagnosis: a practical approach in office practice, Pediatr Clin North Am *50:1019–1048, 2003. Adapted from Reiff MI: Attention-deficit/hyperactivity disorders. In Bergman AB, editor:* 20 Common problems in pediatrics, *New York, 2001, McGraw-Hill, p 273.*

Behavior Rating Scales

Behavior rating scales are useful in establishing the magnitude and pervasiveness of the symptoms, but are not sufficient alone to make a diagnosis of ADHD. There are a variety of well-established behavior rating scales that have obtained good results in discriminating between children with ADHD and control subjects. These measures include, but are not limited to, the Vanderbilt ADHD Diagnostic Rating Scale; the Conner Rating Scales (parent and teacher); the ADHD Index; the Swanson, Nolan, and Pelham Checklist (SNAP); and the ADD-H: Comprehensive Teacher Rating Scale (ACTeRS). Other broadband checklists, such as the Achenbach Child Behavior Checklist (CBCL) or Behavioral Assessment Scale for Children (BASC), are useful, particularly in instances where the child may be experiencing co-occurring problems in other areas (anxiety, depression, conduct problems). Some, such as the BASC, include a validation scale to help determine the reliability of a given observer's assessment of the child.

Physical Examination and Laboratory Findings

There are no standard laboratory tests available to identify ADHD in children. The presence of hypertension, ataxia, or a thyroid disorder should prompt further diagnostic evaluation. Impaired fine motor movement and poor coordination and other **subtle neurologic motor signs** (difficulties with finger tapping, alternating movements, finger-to-nose, skipping, tracing a maze, cutting paper) are common, but they are not sufficiently specific to contribute to a diagnosis of ADHD. The clinician should also identify any possible vision or hearing problems. The clinician should consider testing for elevated lead levels in children who present with some or all of the diagnostic criteria, if these children are exposed to environmental factors that might put them at risk (substandard housing, old paint, proximity to a highway which led to deposition of lead in the topsoil from automobile exhaust years ago). Behavior in the structured laboratory setting might not reflect the child's typical behavior in the home or school environment. Therefore, reliance on observed behavior in a physician's office can result in an incorrect diagnosis. Computerized attentional tasks and electroencephalographic assessments are not needed to make the diagnosis, and compared to the clinical gold standard they are subject to false-positive and false-negative errors. Nonetheless, the FDA has approved the Neuropsychiatric EEG-Based Assessment Aide (NEBA) system, which may identify an abnormal theta : beta wave ratio associated with ADHD.

Differential Diagnosis

Chronic illnesses, such as migraine headaches, absence seizures, asthma and allergies, hematologic disorders, diabetes, childhood cancer, affect up to 20% of children in the United States and can impair children's attention and school performance, either because of the disease itself or because of the medications used to treat or control the underlying illness (medications for asthma, steroids, anticonvulsants, antihistamines) (see Table 33-3). In older children and adolescents, **substance abuse** (see Chapter 114) can result in declining school performance and inattentive behavior.

Sleep disorders, including those secondary to chronic upper airway obstruction from enlarged tonsils and adenoids, often result in behavioral and emotional symptoms, although such problems are not likely to be principal contributing causes of ADHD (see Chapter 19). Periodic leg movements of sleep/restless leg syndrome is associated with attentional symptoms, and inquiry regarding this should be made during the history. Behavioral and emotional disorders can cause disrupted sleep patterns as well.

Depression and anxiety disorders (see Chapters 25 and 26) can cause many of the same symptoms as ADHD (inattention, restlessness, inability to focus and concentrate on work, poor organization, forgetfulness), but can also be comorbid conditions. Obsessive-compulsive disorder can mimic ADHD, particularly when recurrent and persistent thoughts, impulses, or images are intrusive and interfere with normal daily activities. Adjustment disorders secondary to major life stresses (death of a close family member, parents' divorce, family violence, parents' substance abuse, a move, shared social trauma such as bombings or other attacks) or parent–child relationship disorders involving conflicts over discipline, overt child abuse and/or neglect, or overprotection can result in symptoms similar to those of ADHD.

Although ADHD is believed to result from primary impairment of attention, impulse control, and motor activity, there is a high prevalence of comorbidity with other neuropsychiatric disorders (see Table 33-3). Of children with ADHD, 15-25% have learning disabilities, 30-35% have developmental language disorders, 15-20% have

diagnosed mood disorders, and 20-25% have coexisting anxiety disorders. Children with ADHD can also have co-occurring diagnoses of sleep disorders, memory impairment, and decreased motor skills.

TREATMENT

Psychosocial Treatments

Once the diagnosis of ADHD is established, the caregiver should discuss with the parents and child the ways ADHD can affect learning, behavior, self-esteem, social skills, and family function. The clinician should set goals for the family to improve the child's interpersonal relationships, develop study skills, and decrease disruptive behaviors. Parent support groups with appropriate professional consultation to such groups can be very helpful.

Behaviorally Oriented Treatments

Treatments geared toward behavioral management often occur in the time frame of 8-12 sessions. The goal of such treatment is for the clinician to identify targeted behaviors that cause impairment in the child's life (disruptive behavior, difficulty in completing homework, failure to obey home or school rules) and for the child to work on progressively improving the child's skill in these areas. The clinician should guide the parents and teachers in implementing rules, consequences, and rewards to encourage desired behaviors. In short-term comparison trials, stimulants have been more effective than behavioral treatments used alone; behavioral interventions are only modestly successful at improving behavior, but they may be particularly useful for children with complex comorbidities and family stressors, when combined with medication.

Medications

The most widely used medications for the treatment of ADHD and the treatment of choice are the presynaptic dopaminergic agonists, commonly called psychostimulant medications, including methylphenidate (Ritalin, Concerta, Metadate, Focalin, Daytrana), amphetamine, and/or various amphetamine and dextroamphetamine preparations (Dexedrine, Adderall, Vyvanse) (Table 33-4). Longer-acting, once-daily forms of each of the major types of stimulant medications are available and facilitate compliance with treatment and coverage over a longer period of time. The clinician should prescribe a stimulant treatment, either methylphenidate or an amphetamine compound. If a full range of methylphenidate dosages is used, approximately 25% of patients have an optimal response on a low (<0.5 mg/kg/day for methylphenidate, <0.25 mg/kg/day for amphetamines), 25% on medium (0.5-1.0 mg/kg/day for methylphenidate, 0.25-0.5 mg/kg/day for amphetamines), or high (1.0-1.5 mg/day for methylphenidate, 0.5-0.75 mg/kg/day for amphetamine) daily dosage; another 25% will be unresponsive or will have side effects, making that drug particularly unpalatable for the family.

Over the first 4 wk of treatment, the physician should increase the medication dose as tolerated (keeping side effects minimal to absent) to achieve maximum benefit. If this strategy does not yield satisfactory results, or if side effects prevent further dose adjustment in the presence of persisting symptoms, the clinician should use an alternative class of stimulants that was not used previously. If a methylphenidate compound is unsuccessful, the clinician should switch to an amphetamine product. If satisfactory treatment results are not obtained with the second stimulant, clinicians may choose to prescribe atomoxetine, a noradrenergic reuptake inhibitor that is superior to placebo in the treatment of ADHD in children, adolescents, and adults and that has been approved by the FDA for this indication. Atomoxetine should be initiated at a dose of 0.3 mg/kg/day and titrated over 1-3 wk to a maximum total daily dosage of 1.2-1.8 mg/kg/day. The dose should be divided into twice-daily portions. Once-daily dosing appears to be associated with a high incidence of treatment failure. Guanfacine, originally developed as an antihypertensive agent, is also FDA approved for the treatment of ADHD, although it appears to be less successful for hyperactivity and more likely to assist with impulsivity. It can also treat motor and vocal tics, and so may be a reasonable choice in a child with a comorbid tic disorder.

The clinician should recognize that careful monitoring of medication is a necessary component of treatment in children with ADHD. When physicians prescribe medications for the treatment of ADHD, they tend to use lower-than-optimal doses. Optimal treatment usually requires somewhat higher doses than those typically used in routine practice settings. All-day preparations are also useful to maximize positive effects and minimize side effects, and regular medication follow-up visits should be offered (4 or more times per year) as opposed to the twice-yearly medication visits often used in standard community-care settings.

Medication alone is not always sufficient to treat ADHD in children, particularly in instances where children have multiple psychiatric disorders or stressed home environments. When children do not respond to medication, it may be appropriate to refer them to a mental health specialist. Consultation with a child psychiatrist or psychologist can also be beneficial to determine the next steps for treatment, including adding other components and supports to the overall treatment program. Evidence suggests that children who receive careful medication management, accompanied by frequent treatment follow-up, all within the context of an educative, supportive relationship with the primary care provider, are likely to experience behavioral gains for up to 24 mo.

Stimulant drugs used to treat ADHD may be associated with an increased risk of adverse cardiovascular events, including sudden cardiac death, myocardial infarction, and stroke in young adults and rarely in children. In some of the reported cases, the patient had an underlying disorder, such as hypertrophic obstructive cardiomyopathy, which is made worse by sympathomimetic agents. These events are rare, but they nonetheless warrant consideration before initiating treatment and during monitoring of treatment with stimulant medications. Children with a positive or personal family history of cardiomyopathy, or arrhythmias, or syncope require an electrocardiogram and possible cardiology consultation before a stimulant is prescribed (Fig. 33-1).

PROGNOSIS

A childhood diagnosis of ADHD often leads to persistent ADHD throughout the life span. From 60-80% of children with ADHD continue to experience symptoms in adolescence, and up to 60% of adolescents exhibit ADHD symptoms into adulthood. In children with ADHD, a reduction in hyperactive behavior often occurs with age. Other symptoms associated with ADHD can become more prominent with age, such as inattention, impulsivity, and disorganization, and

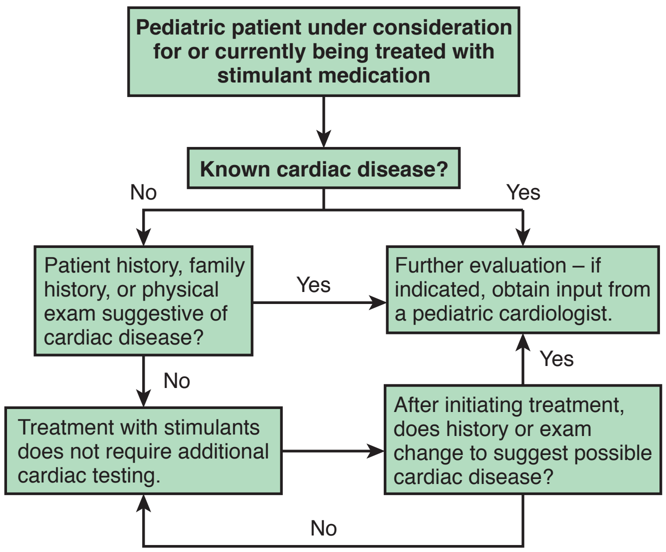

Figure 33-1 Cardiac evaluation of children and adolescents receiving or being considered for stimulant medications. *(From Perrin JM, Friedman RA, Knilans TK: Cardiovascular monitoring and stimulant drugs for attention-deficit/hyperactivity disorder,* Pediatrics *122:451–453, 2008.)*

Table 33-4 Medications Used in the Treatment of Attention-Deficit/Hyperactivity Disorder

GENERIC NAME	BRAND NAME	DURATION	DOSAGE RANGE	SIDE EFFECTS
METHYLPHENIDATE				
Immediate-release	Ritalin, Methylin	3-4 hr	5, 10, 20 mg tabs	Moderate appetite suppression, mild sleep disturbances, transient weight loss, irritability, emergence of tics, priapism
Extended-release	Metadate ER, Methylin ER,	4-6 hr	10, 20 mg extended-release tabs	Moderate appetite suppression, mild sleep disturbances, transient weight loss, irritability, emergence of tics, priapism
	Metadate-CD	8-10 hr	10, 20, 30 mg extended-release caps	
	Ritalin LA	8-10 hr	20, 30, 40 mg caps	
	Concerta	10-12 hr	18, 27, 36, 54 mg caps	Moderate appetite suppression, mild sleep disturbances, transient weight loss, irritability, emergence of tics
Sustained-release	Ritalin SR, Methylphenidate SR	4-6 hr	20 mg sustained-release tabs	Moderate appetite suppression, mild sleep disturbances, transient weight loss, irritability, emergence of tics, priapism
Transdermal system	Daytrana	≥12 hr	Patch	Moderate appetite suppression, mild sleep disturbances, transient weight loss, irritability, emergence of tics, priapism
DEXMETHYLPHENIDATE				
	Focalin	4-6 hr	2.5, 5, 10 mg tabs	Moderate appetite suppression, mild sleep disturbances, transient weight loss, irritability, emergence of tics
Extended-release	Focalin XR	6-8 hr		Moderate appetite suppression, mild sleep disturbances, transient weight loss, irritability, emergence of tics
DEXTROAMPHETAMINE				
Short-acting	Dexedrine, DextroStat	4-6 hr	5, 10, 15 mg tabs	Moderate appetite suppression, mild sleep disturbances, transient weight loss, irritability, emergence of tics
Intermediate-acting	Dexedrine, Spansule	6-8 hr	5, 10, 20 mg tabs	Moderate appetite suppression, mild sleep disturbances, transient weight loss, irritability, emergence of tics
Lisdexamfetamine	Vyvanse	≤12 hr	30 mg, 50 mg, 70 mg tablets	Moderate appetite suppression, mild sleep disturbances, transient weight loss, irritability, emergence of tics
MIXED AMPHETAMINE SALTS				
Intermediate-acting	Adderall	4-6 hr	5, 10, 20 mg tabs	Moderate appetite suppression, mild sleep disturbances, transient weight loss, irritability, emergence of tics
Extended-release	Adderall XR	8-12 hr	5, 10, 15, 20, 25, 30 mg caps	Moderate appetite suppression, mild sleep disturbances, transient weight loss, irritability, emergence of tics
ATOMOXETINE				
Extended-release	Strattera	12 hr	10, 18, 25, 40, 60 mg caps	Nervousness, sleep problems, fatigue, stomach upset, dizziness, dry mouth Can lead in rare cases to severe liver injury or to suicidal ideation
Bupropion	Wellbutrin	4-5 hr	100, 150 mg tabs	Difficulty sleeping, headache, seizures
Bupropion	Wellbutrin SR, Wellbutrin XL		100, 150, 200 mg tabs	
TRICYCLIC ANTIDEPRESSANTS				
Imipramine	Tofranil	Variable	See Table 21-4	Nervousness, sleep problems, fatigue, stomach upset, dizziness, dry mouth, accelerated heart rate
Desipramine*	Norpramin			
Nortriptyline	Aventyl, Pamelor			
α-AGONISTS				
Clonidine	Catapres, Kapvay	6-12 hr	3-10 µg/kg/day bid-qid	Sedation, depression, dry mouth, rebound hypertension on discontinuing, confusion
Guanfacine	Tenex, Intuniv	6-12 hr	1, 2, 3 mg tabs	Hypotension, lightheadedness

cap, capsule; tab, tablet.
*Associated with deaths from cardiac problems. Not recommended for children.

these exact a heavy toll on young adult functioning. A variety of risk factors can affect children with untreated ADHD as they become adults. These risk factors include engaging in risk-taking behaviors (sexual activity, delinquent behaviors, substance use), educational underachievement or employment difficulties, and relationship difficulties. With proper treatment, the risks associated with the disorder can be significantly reduced. It appears that consistent treatment with medication and adjuvant therapies can lower the risk of adverse outcomes, such as substance abuse.

PREVENTION

Parent training can lead to significant improvements in preschool children with ADHD symptoms, and parent training for preschool youth with ADHD can reduce oppositional behavior. To the extent that parents, teachers, physicians, and policymakers support efforts for earlier detection, diagnosis, and treatment, prevention of long-term adverse effects of ADHD on affected children's lives should be reconsidered within the lens of prevention. Given the effective treatments for ADHD now available, and the well-documented evidence about the long-term effects of untreated or ineffectively treated ADHD on children and youth, prevention of these consequences should be within the grasp of physicians and the children and families with ADHD for whom we are responsible.

Chapter **34**

Dyslexia

Sally E. Shaywitz and Bennett A. Shaywitz

Dyslexia is defined in this chapter as an *unexpected difficulty* in reading, that is, unexpected in relation to intelligence, chronological age/grade level, education, or professional status. In typical readers, development of reading and IQ are dynamically linked over time, but in dyslexic readers there is a developmental uncoupling between reading and IQ (Fig. 34-1). These findings provide an explanation for the "unexpected" nature of dyslexia and provide the long sought empirical evidence for the seeming paradox between cognition and reading in individuals with developmental dyslexia.

ETIOLOGY

Dyslexia is both familial and heritable. Dyslexia is observed in 50% of children who have a parent with dyslexia; 50% of the siblings of dyslexic persons; and 50% of the parents of dyslexics. Dyslexia reflects a multifactorial model of the interaction between genetic and environmental factors. Multiple genes can influence the disorder, with each gene individually contributing a small amount of variance and with a single etiologic factor insufficient to cause or explain dyslexia. The neural systems are the final common pathway for multiple influences, and it is unlikely that a single gene or even several genes cause or explain dyslexia.

EPIDEMIOLOGY

Dyslexia is the most common and most comprehensively studied of the **learning disabilities,** affecting 80% of children identified as learning disabled. Dyslexia may be the most common neurobehavioral disorder affecting children, with prevalence rates ranging from 5-10% in clinic- and school-identified samples to 17.5% in unselected population-based samples in the United States and other countries. Dyslexia fits a dimensional model in which reading ability and disability occur along a continuum, with dyslexia representing the lower tail of a normal distribution of reading ability. Although more boys than girls are identified by schools as dyslexic, in studies based on survey samples in which *all* children are assessed, there are no significant gender differences in dyslexia.

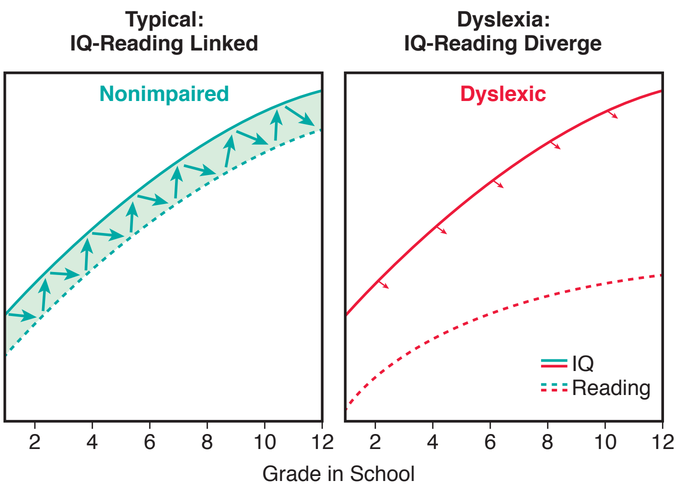

Figure 34-1 **Uncoupling of reading and IQ over time: empirical evidence for a definition of dyslexia.** *Left* panel shows that in typical readers, reading and IQ development are dynamically linked over time. In contrast, *right* panel, dyslexic readers, shows that reading and IQ development are dissociated and one does not influence the other. *(Data adapted from Ferrer E, Shaywitz BA, Holahan JM, et al: Uncoupling of reading and IQ over time: empirical evidence for a definition of dyslexia,* Psychol Sci *21(1):93–101, 2010.)*

PATHOGENESIS

Evidence from a number of lines of investigation indicates that dyslexia reflects deficits within the language system, and more specifically, within the phonologic component of the language system engaged in processing the sounds of speech. Dyslexic individuals have difficulty developing an awareness that spoken words can be segmented into smaller elemental units of sound **(phonemes),** an essential ability given that reading requires that the reader map or link printed symbols to sound. Increasing evidence indicates that disruption of attentional mechanisms may also play an important role in reading difficulties.

Functional brain imaging in both children with dyslexia and adult dyslexic readers demonstrates an inefficient functioning of left hemisphere posterior brain systems, a pattern referred to as the *neural signature of dyslexia* (Fig. 34-2). Although functional MRI consistently demonstrates differences between *groups* of dyslexic compared to typical readers, brain imaging is not able to differentiate an *individual* case of dyslexic reader from a typical reader and so brain imaging is not useful in diagnosing dyslexia.

CLINICAL MANIFESTATIONS

Reflecting the underlying phonologic weakness, children and adults with dyslexia manifest problems in both spoken and written language. Spoken language difficulties are typically manifest by mispronunciations, lack of glibness, speech that lacks fluency with many pauses or hesitations and "ums," word-finding difficulties with the need for time to summon an oral response and the inability to come up with a verbal response quickly when questioned; these reflect sound-based, and not semantic or knowledge-based difficulties.

Struggles in decoding and word recognition can vary according to age and developmental level. The cardinal signs of dyslexia observed in school-age children and adults are a labored, effortful approach to reading involving decoding, word recognition, and text reading. Listening comprehension is typically robust. Older children improve reading accuracy over time, albeit without commensurate gains in reading fluency; they remain slow readers. Difficulties in spelling typically reflect the phonologically based difficulties observed in oral reading. Handwriting is often affected as well.

History often reveals early subtle language difficulties in dyslexic children. During the preschool and kindergarten years, at-risk children display difficulties playing rhyming games and learning the names for letters and numbers. Kindergarten assessments of these language skills can help identify children at risk for dyslexia. Although a dyslexic child enjoys and benefits from being read to, the child might avoid reading aloud to the parent or reading independently.

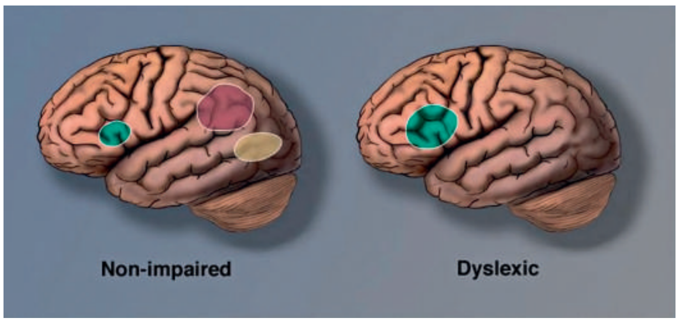

Figure 34-2 **A neural signature for dyslexia.** The *left* side of the figure shows a schematic of left hemisphere brain systems in in typical (non-impaired) readers. The 3 systems for reading are an anterior system in the region of the inferior frontal gyrus (Broca's area), serving articulation and word analysis, and 2 posterior systems, 1 in the occipitotemporal region serving word analysis, and a second in the occipitotemporal region (the word-form area) serving the rapid, automatic, fluent identification of words. In dyslexic readers (*right* side of figure), the 2 posterior systems are functioning inefficiently and appear underactivated. This pattern of underactivation in left posterior reading systems is referred to as the neural signature for dyslexia. *(Adapted from Shaywitz S:* Overcoming dyslexia: a new and complete science-based program for reading problems at any level. *New York, 2003, Alfred A. Knopf. Copyright 2003 by S. Shaywitz. Adapted with permission.)*

Dyslexia may co-occur with attention-deficit/hyperactivity disorder (see Chapter 33); this comorbidity has been documented in both referred samples (40% comorbidity) and nonreferred samples (15% comorbidity).

DIAGNOSIS

Dyslexia is a clinical diagnosis, and history is especially critical. The clinician seeks to determine through history, observation, and psychometric assessment, if there are unexpected difficulties in reading (based on the person's intelligence, chronological/grade, level of education or professional status) and associated linguistic problems at the level of phonologic processing. There is no single test score that is pathognomonic of dyslexia. The diagnosis of dyslexia should reflect a thoughtful synthesis of all clinical data available.

Dyslexia is distinguished from other disorders that can prominently feature reading difficulties by the unique, circumscribed nature of the phonologic deficit, one that does not intrude into other linguistic or cognitive domains. Family history, teacher and classroom observation, and tests of language (particularly phonology), reading including fluency, and spelling represent a core assessment for the diagnosis of dyslexia in children; additional tests of intellectual ability, attention, memory, general language skills, and mathematics may be administered as part of a more comprehensive evaluation of cognitive, linguistic, and academic function. Once a diagnosis has been made, dyslexia is a permanent diagnosis and need not be reconfirmed by new assessments.

For informal screening, in addition to a careful history, the primary care physician in an office setting can listen to the child read aloud from the child's own grade-level reader. Keeping a set of graded readers available in the office serves the same purpose and eliminates the need for the child to bring in schoolbooks. Oral reading is a sensitive measure of reading accuracy and fluency. The most consistent and telling sign of a reading disability in an accomplished young adult is slow and laborious reading and writing. In attempting to read aloud, most children and adults with dyslexia display an effortful approach to decoding and recognizing single words, an approach in children characterized by hesitations, mispronunciations, and repeated attempts to sound out unfamiliar words. In contrast to the difficulties they experience in decoding single words, persons with dyslexia typically possess the vocabulary, syntax, and other higher-level abilities involved in comprehension.

The failure either to recognize or to measure the lack of fluency in reading is perhaps the most common error in the diagnosis of dyslexia in older children and accomplished young adults. Simple word identification tasks will not detect dyslexia in a person who is accomplished enough to be in honors high school classes or to graduate from college or obtain a graduate degree. Tests relying on the accuracy of word identification alone are inappropriate to use to diagnose dyslexia because they show little to nothing of the struggle to read. Because they assess reading accuracy but not automaticity (speed), the kinds of reading tests commonly used for school-age children might provide misleading data on bright adolescents and young adults. The most critical tests are those that are timed; they are the most sensitive in detecting dyslexia in a bright adult. There are few standardized tests for young adult readers that are administered under timed and untimed conditions; the Nelson-Denny Reading Test is an exception. The helpful Test of Word Reading Efficiency (TOWRE) examines simple word reading under timed conditions. Any scores obtained on testing must be considered relative to peers with the same degree of education or professional training.

MANAGEMENT

The management of dyslexia demands a life-span perspective. Early on, the focus is on remediation of the reading problem. Application of knowledge of the importance of early language, including vocabulary and phonologic skills, leads to significant improvements in children's reading accuracy, even in predisposed children. As a child matures and enters the more time-demanding setting of secondary school, the emphasis shifts to the important role of providing accommodations. Based on the work of the National Reading Panel, evidence-based reading intervention methods and programs are identified. Effective intervention programs provide systematic instruction in 5 key areas: phonemic awareness, phonics, fluency, vocabulary, and comprehension strategies. These programs also provide ample opportunities for writing, reading, and discussing literature.

Taking each component of the reading process in turn, effective interventions improve **phonemic awareness:** the ability to focus on and manipulate phonemes (speech sounds) in **spoken** syllables and words. The elements found to be most effective in enhancing phonemic awareness, reading, and spelling skills include teaching children to manipulate phonemes with letters; focusing the instruction on 1 or 2 types of phoneme manipulations rather than multiple types; and teaching children in small groups. Providing instruction in phonemic awareness is necessary but not sufficient to teach children to read. Effective intervention programs include teaching **phonics,** or making sure that the beginning reader understands how letters are linked to sounds (phonemes) to form letter-sound correspondences and spelling patterns. The instruction should be explicit and systematic; phonics instruction enhances children's success in learning to read, and systematic phonics instruction is more effective than instruction that teaches little or no phonics or teaches phonics casually or haphazardly.

Fluency is of critical importance because it allows the automatic, rapid recognition of words and while it is generally recognized that fluency is an important component of skilled reading, it has proven difficult to teach. Interventions for **vocabulary development and reading comprehension** are not as well established. The most effective methods to teach reading comprehension involve teaching **vocabulary** and **strategies** that encourage active interaction between the reader and the text. Emerging science indicates that it is not only teacher content knowledge but the teacher's skill in engaging the student and focusing the student's attention on the reading task at hand that is required for effective instruction.

For those in high school, college, and graduate school, provision of accommodations most often represents a highly effective approach to dyslexia. Imaging studies now provide neurobiologic evidence for the need for extra time for dyslexic students; accordingly, college students with a childhood history of dyslexia require extra time in reading and writing assignments as well as examinations. Many adolescent and adult students have been able to improve their reading accuracy but without commensurate gains in reading speed. The accommodation of extra time reconciles the individual's often high cognitive ability and slow reading so that the exam is a measure of that person's ability rather than his disability. Another important accommodation is teaching the dyslexic student to listen to texts. Programs such as Kurzweil, WYNN, Learning Ally, and Bookshare are available, as are programs such as Dragon Dictate that provide voice-to-text conversion. Other helpful accommodations include the use of laptop computers with spelling checkers, access to lecture notes, tutorial services, and a separate quiet room for taking tests. In addition, the impact of the primary phonologic weakness mandates special consideration during oral examinations so that students are not graded on their lack of glibness or speech hesitancies but on their content knowledge. Unfortunately, often speech hesitancies or difficulties in word retrieval are wrongly confused with insecure content knowledge.

PROGNOSIS

Application of evidence-based methods to young children (kindergarten to grade 3), when provided with sufficient intensity and duration, can result in improvements in reading accuracy and, to a much lesser extent, fluency. In older children and adults, interventions result in improved accuracy, but not an appreciable improvement in fluency. Accommodations are critical in allowing the dyslexic child to demonstrate his or her knowledge. Parents should be informed that with proper support, dyslexic children can succeed in a range of future occupations that might seem out of the reach of dyslexic children including medicine, law, journalism, and writing.

Chapter **35**

Language Development and Communication Disorders

Mark D. Simms

Most children learn to communicate in their native language without specific instruction or intervention other than exposure to a language-rich environment. Normal development of speech and language is predicated on the infant's ability to hear, see, comprehend, remember, and socially interact with others. The infant must also possess sufficient motor skills to imitate oral motor movements.

NORMAL LANGUAGE DEVELOPMENT

Language can be subdivided into several essential components. **Communication** consists of a wide range of behaviors and skills. At the level of basic verbal ability, **phonology** refers the correct use of speech sounds to form words, **semantics** refers to the correct use of words, and **syntax** refers to the appropriate use of grammar to make sentences. At a more abstract level, verbal skills include the ability to link thoughts together in a coherent fashion and to maintain a topic of conversation. **Pragmatic** abilities include verbal and nonverbal skills that facilitate the exchange of ideas, including the appropriate choice of language for the situation and circumstance and the appropriate use of body language (i.e., posture, eye contact, gestures). Social pragmatic and behavioral skills also play an important role in effective interactions with communication partners (i.e., engaging, responding, and maintaining reciprocal exchanges).

It is customary to divide language skills into receptive (hearing and understanding) and expressive (talking) abilities. Language development usually follows a fairly predictable pattern and parallels general intellectual development (Table 35-1).

Receptive Language Development

The peripheral auditory system is mature by 26 wk gestation and the fetus responds to and discriminates speech sounds. Anatomical asymmetry in the *planum temporale*, the structural brain region specialized for language processing, is present by 31 wk gestation. At birth, the full-term newborn appears to have functionally organized neural networks that are sensitive to different properties of language input. The normal newborn demonstrates preferential response to human voices over inanimate sound, and recognizes the mother's voice, reacting stronger to it than to a stranger's voice. Even more remarkable is the ability of the newborn to discriminate sentences in their "native" (mother's) language from sentences in a "foreign" language. In research settings, infants of monolingual mothers showed a preference only for that language, while infants of bilingual mothers showed a preference for both exposed languages over any other language.

Between 4 and 6 mo, infants visually search for the source of sounds, again showing a preference for the human voice over other environmental sounds. By 5 mo, infants can passively follow the adult's line of visual regard, resulting in a "joint reference" to the same objects and events in the environment. The ability to share the same experience is critical to the development of further language, social, and cognitive skills as the infant "maps" specific meanings onto his or her experiences. By 8 mo, the infant can actively show, give, and point to objects. Comprehension of words often becomes apparent by 9 mo, when the infant selectively responds to his or her name and appears to comprehend the word "no." Social games, such as "peek-a-boo," "so big," and waving "bye-bye" can be elicited by simply mentioning the words. At 12 mo, many children can follow a simple, one-step request without a gesture (e.g., "Give it to me!").

Between 1 and 2 yr, comprehension of language accelerates rapidly. Toddlers can point to body parts on command, identify pictures in books when named, and respond to simple questions (e.g., "Where's your shoe?"). The 2 yr old is able to follow a 2-step command, employing unrelated tasks (e.g., "Take off your shoes, then go sit at the table"), and can point to objects described by their use (e.g., "Give me the one we drink from"). By 3 yr, children typically understand simple "wh-" question forms (e.g., who, what, where, why). By 4 yr, most children can follow adult conversation. They can listen to a short story and answer simple questions about it. Five yr olds typically have a receptive vocabulary of more than 2000 words and can follow 3- and 4-step commands.

Expressive Language Development

Cooing noises are established by 4-6 wk of age. Over the first 3 mo of life, parents may distinguish their infant's different vocal sounds for pleasure, pain, fussing, tiredness, etc. Many 3 mo old infants vocalize in a reciprocal fashion with an adult to maintain a social interaction ("vocal tennis"). By 4 mo, infants begin to make bilabial ("raspberry") sounds, and by 5 mo, monosyllables and laughing are noticeable. Between 6 and 8 mo, polysyllabic babbling ("lalala" or "mamama") is heard and the infant might begin to communicate with gestures. Between 8 and 10 mo, babbling makes a phonologic shift toward the particular sound patterns of the child's native language (i.e., they produce more native sounds than nonnative sounds). At 9-10 mo, babbling becomes truncated into specific words (e.g., "mama," or "dada") for their parents.

Over the next several months, infants learn 1 or 2 words for common objects and begin to imitate words presented by an adult. These words might appear to come and go from the child's repertoire until a stable group of 10 or more words is established. The rate of acquisition of new words is approximately 1 new word per wk at 12 mo, but it accelerates to approximately 1 new word per day by 2 yr. The first words to appear are used primarily to label objects (nouns) or to ask for objects and people (requests). By 18-20 mo, toddlers should use a minimum of 20 words and produce jargon (strings of word-like sounds) with language-like inflection patterns (rising and falling speech patterns). This jargon usually contains some embedded true words. Spontaneous 2-word phrases (pivotal speech), consisting of the flexible juxtaposition of words with clear intention (e.g., "Want juice!" or "Me down!"), is characteristic of 2 yr olds and reflects the emergence of grammatical ability (syntax).

Two-word, combinational phrases do not usually emerge until the child has acquired 50-100 words in their lexicon. Thereafter, the acquisition of new words accelerates rapidly. As knowledge of grammar increases, there is a proportional increase in verbs, adjectives, and other words that serve to define the relation between objects and people (predicates). By 3 yr, sentence length increases and the child uses pronouns and simple present tense verb forms. These 3-5 word sentences typically have a subject and verb but lack conjunctions, articles, and complex verb forms. The Sesame Street character Cookie Monster ("Me want cookie!") typifies the "telegraphic" nature of the 3 yr old's sentences. By 4-5 yr, children should be able to carry on conversations using adult-like grammatical forms and use sentences that provide details (e.g., "I like to read my books").

Variations of Normal

Language milestones have been found to be largely universal across languages and cultures, with some variations depending on the complexity of the grammatical structure of individual languages. In Italian (where verbs often occupy a prominent position at the beginning or end of sentences), 14 month-olds produce a greater proportion of verbs compared with English speaking infants. Within a given language, development usually follows a fairly predictable pattern, paralleling general cognitive development. Although the sequences are predictable, the exact timing of achievement is not. There are marked variations among normal children in the rate of development of babbling, comprehension of words, production of single words, and use of combinational forms within the first 2-3 yr of life.

Table 35-1 Normal Language Milestones

HEARING AND UNDERSTANDING	TALKING
BIRTH TO 3 MONTHS	
Startles to loud sounds Quiets or smiles when spoken to Seems to recognize your voice and quiets if crying Increases or decreases sucking behavior in response to sound	Makes pleasure sounds (cooing, gooing) Cries differently for different needs Smiles when sees you
4-6 MO	
Moves eyes in direction of sounds Responds to changes in tone of your voice Notices toys that make sounds Pays attention to music	Babbling sounds more speech-like, with many different sounds, including *p*, *b*, and *m* Vocalizes excitement and displeasure Makes gurgling sounds when left alone and when playing with you
7 MO-1 YEAR	
Enjoys games such as peekaboo and pat-a-cake Turns and looks in direction of sounds Listens when spoken to Recognizes words for common items, such as *cup*, *shoe*, and *juice* Begins to respond to requests *(Come here. Want more?)*	Babbling has both long and short groups of sounds, such as *tata upup bibibibi.* Uses speech or noncrying sounds to get and keep attention Imitates different speech sounds Has 1 or 2 words *(bye-bye, Dada, Mama),* although they might not be clear
1-2 YR	
Points to a few body parts when asked Follows simple commands and understands simple questions *(Roll the ball. Kiss the baby. Where's your shoe?)* Listens to simple stories, songs, and rhymes Points to pictures in a book when named	Says more words every month Uses some 1-2 word questions *(Where kitty? Go bye-bye? What's that?)* Puts 2 words together *(more cookie, no juice, mommy book)* Uses many different consonant sounds at the beginning of words
2-3 YR	
Understands differences in meaning (e.g., go–stop, in–on, big–little, up–down) Follows 2-step requests *(Get the book and put it on the table.)*	Has a word for almost everything Uses 2-3 word "sentences" to talk about and ask for things Speech is understood by familiar listeners most of the time Often asks for or directs attention to objects by naming them
3-4 YR	
Hears you when you call from another room Hears television or radio at the same loudness level as other family members Understands simple *who, what, where, why* questions	Talks about activities at school or at friends' homes Usually understood by people outside the family Uses a lot of sentences that have ≥4 words Usually talks easily without repeating syllables or words
4-5 YR	
Pays attention to a short story and answers simple questions about it Hears and understands most of what is said at home and in school	Voice sounds as clear as other children's Uses sentences that include details *(I like to read my books.)* Tells stories that stick to a topic Communicates easily with other children and adults Says most sounds correctly except a few, such as *l, s, r, v, z, ch, sh,* and *th* Uses the same grammar as the rest of the family

Adapted from American Speech-Language-Hearing Association, 2005. http://www.asha.org/public/speech/development/chart.htm.

Two basic patterns of language learning have been identified: "analytic" and "holistic." The analytic pattern is the most common and reflects the mastery of increasingly larger units of language form. As reflected in the previous discussion of milestones, the child's analytic skills proceed from simple to more complex and lengthy forms. Children who follow a holistic or gestalt learning pattern might start by using relatively large chunks of speech in familiar contexts. They might memorize familiar phrases or dialogs from movies or stories and repeat them in an over-generalized fashion. Their sentences often have a formulaic pattern, reflecting inadequate mastery of the use of grammar to flexibly and spontaneously combine words appropriately in the child's own unique utterance. Over time, these children gradually break down the meanings of phrases and sentences into their component parts, and they learn to analyze the linguistic units of these memorized forms. As this occurs, more original speech productions emerge and the child is able to assemble thoughts in a more flexible manner. Both analytic and holistic learning processes are necessary for normal language development to occur.

LANGUAGE AND COMMUNICATION DISORDERS

Epidemiology

Disorders of speech and language are very common in preschool-age children. Nearly 20% of 2 yr olds are thought to have delayed onset of speech. By age 5 yr, approximately 6% of children are identified as having a speech impairment, 5% as having both speech and language impairment, and 8% as having language impairment. Boys are nearly twice as likely to have an identified speech or language impairment as girls.

Etiology

Normal language ability is a complex function that is widely distributed across the brain through interconnected neural networks that are synchronized for specific activities. Although there are clinical similarities between acquired aphasia in adults and childhood language disorders, unilateral, focal lesions acquired in early life do not seem to have the same effects in children as in adults. Risk factors for neurologic injury are absent in the vast majority of children with language impairment.

Genetic factors appear to play a major role in influencing how children learn to talk. Language disorders cluster in families. A careful family history may identify current or past speech or language problems in up to 30% of 1st-degree relatives of proband children. Although children who are exposed to parents with language difficulty might be expected to experience poor language stimulation and inappropriate language modeling, studies of twins have shown the concordance rate for low language test score and/or a history of speech therapy to be approximately 50% in dizygotic pairs, rising to over 90% in

monozygotic pairs. A number of potential gene loci have been identified, but no consistent genetic markers have been established.

The most plausible genetic mechanism involves a disruption in the timing of early prenatal neurodevelopmental events affecting migration of nerve cells from the germinal matrix to the cerebral cortex. Chromosomal lesions and point mutations of the *FOXP2* gene and polymorphisms of the *CNTNAP2* gene are associated with an uncommon but distinct speech and language disorder characterized by difficulties in learning and producing oral movement sequences (childhood apraxia of speech). Affected children have a spectrum of impairment in expressive and receptive language as well as problems understanding grammar.

Pathogenesis

Language disorders are associated with a fundamental deficit in the brain's capacity to process complex information rapidly. Simultaneous evaluation of words (semantics), sentences (syntax), prosody (tone of voice), and social cues can overtax the child's ability to comprehend and respond appropriately in a verbal setting. Limitations in the amount of information that can be stored in verbal working memory can further limit the rate at which language information is processed. Electrophysiologic studies show abnormal latency in the early phase of auditory processing in children with language disorders. Neuroimaging studies identify an array of anatomic abnormalities in regions of the brain that are central to language processing. MRI scans in children with **specific language impairment (SLI)** may reveal white matter lesions, white matter volume loss, ventricular enlargement, focal gray matter heterotopia within the right and left parietotemporal white matter, abnormal morphology of the inferior frontal gyrus, atypical patterns of asymmetry of language cortex, or increased thickness of the corpus callosum in a minority of affected children. Postmortem studies of children with language disorders found evidence of atypical symmetry in the plana temporale and cortical dysplasia in the region of the Sylvian fissure. A high incidence of paroxysmal electroencephalogram (EEG) anomalies during sleep has been identified in children with SLI. Although these findings might represent a mild variant of the Landau-Kleffner syndrome (acquired verbal auditory agnosia), they likely represent an epiphenomenon in which paroxysmal activity is related to architectural dysplasia. In support of a genetic mechanism affecting cerebral development, a high rate of atypical perisylvian asymmetries has also been documented in the parents of children with SLI.

Clinical Manifestations

Primary disorders of speech and language development are often found in the absence of more generalized cognitive or motor dysfunction. Disorders of communication are the most common comorbid condition in persons with generalized cognitive disorders (intellectual disability or autism), structural anomalies of the organs of speech (velopharyngeal insufficiency from cleft palate), and neuromotor conditions affecting oral motor coordination (dysarthria from cerebral palsy or other neuromuscular disorders).

Classification

Each professional discipline has adopted a somewhat different classification system, based on cluster patterns of symptoms. The American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) organized communication disorders into: (1) language disorder (which combines expressive and mixed receptive-expressive language disorders), speech sound disorder (phonologic disorder), and childhood-onset fluency disorder (stuttering); and (2) social (pragmatic) communication disorder, which is persistent difficulties in the social uses of verbal and nonverbal communication (Table 35-2). In clinical practice, childhood speech and language disorders occur as a number of distinct entities.

Specific Language Impairment

Also referred to as **developmental dysphasia**, or developmental language disorder, SLI is characterized by a significant discrepancy between the child's overall cognitive level (typically nonverbal measures of intelligence) and functional language level. These children also follow an atypical pattern of language acquisition and use. Closer examination of the child's skills might reveal deficits in understanding and use of word meaning (semantics) and grammar (syntax). Often, children with SLI are delayed in starting to talk. Most significantly, they usually have difficulty understanding spoken language. The problem may stem from insufficient understanding of single words or from the inability to deconstruct and analyze the meaning of sentences. Many affected children show a holistic pattern of language development, repeating memorized phrases or dialog from movies or stories (echolalia). In contrast to their difficulty with spoken language, children with SLI appear to learn visually and demonstrate their ability on nonverbal tests of intelligence.

After children with SLI become fluent talkers, they are generally less proficient at producing oral narratives compared with their peers. Their stories tend to be shorter and include fewer propositions, main story ideas, or story grammar elements. Older children include fewer mental state descriptions (e.g., references to what their characters think and how they feel). Their narratives contain fewer cohesive devices and the story line may be difficult to follow.

Although they have difficulty interacting with peers who are more verbally adept, many children with SLI play appropriately with younger or older children. Despite their communication impairment, they engage in pretend play, show imagination, share emotions (affective reciprocity), and demonstrate joint referencing behaviors appropriate to their age. Of note is the high incidence of fine motor coordination difficulty found in these children. A combination of increased joint mobility and mild muscular hypotonia often results in motor clumsiness.

Many children with SLI show difficulties with social interaction, particularly with same-age peers. Social interaction is mediated by oral communication, and a child deficient in communication is at a distinct disadvantage in the social arena. Children with SLI tend to be more dependent on older children or adults, who can adapt their communication to match the child's level of function. Generally, social interaction skills are more closely correlated with language level than with nonverbal cognitive level. Using this as a guide, one usually sees a developmental progression of increasingly more sophisticated social interaction as the child's language abilities improve. In this context, social ineptitude is not necessarily a sign of asocial distancing (e.g., autism) but rather a delay in the ability to negotiate social interactions.

Higher-Level Language Disorder

As children mature, the ability to communicate effectively with others depends on mastery of a range of skills that go beyond basic understanding of words and rules of grammar. Higher-level language skills include the development of advanced vocabulary, the understanding of word relationships, reasoning skills (including drawing correct inferences and conclusions), the ability to understand things from another person's perspective, and the ability to paraphrase and rephrase with ease. In addition, higher-order language abilities include pragmatic skills that serve as the foundation for social interactions. These skills include knowledge and understanding of one's conversational partner, knowledge of the social context in which the conversation is taking place, and general knowledge of the world. Social and linguistic aspects of communication are often difficult to separate, and persons who have trouble interpreting these relatively abstract aspects of communication typically experience difficulty forming and maintaining relationships. DSM-5 Identified Social (Pragmatic) Communication Disorder (SPCD) as a category of communication disorder (Table 35-2). Symptoms of pragmatic difficulty include extreme literalness and inappropriate verbal and social interactions. Proper use and understanding of humor, slang, and sarcasm depend on correct interpretation of the meaning and the context of language and the ability to draw proper inferences. Failure to provide a sufficient referential base to one's conversational partner—to take the perspective of another person—results in the appearance of talking or behaving randomly or incoherently. SPCD often occurs in the context of SLI and autism spectrum disorder (ASD) and it has been recognized as a symptom of a wide range of disorders, including right-hemisphere damage to the

Table 35-2 DSM-5 Diagnostic Criteria for Communication Disorders

Language Disorder	A. Persistent difficulties in the acquisition and use of language across modalities (i.e., spoken, written, sign language, or other) due to deficits in comprehension or production that include the following: 1. Reduced vocabulary (word knowledge and use) 2. Limited sentence structure (ability to put words and word endings together to form sentences based on the rules of grammar and morphology). 3. Impairments in discourse (ability to use vocabulary and connect sentences to explain or describe a topic or series of events or have a conversation). B. Language abilities are substantially and quantifiably below those expected for age, resulting in functional limitations in effective communication, social participation, academic achievement, or occupational performance, individually or in any combination. C. Onset of symptoms is in the early developmental period. D. The difficulties are not attributable to hearing or other sensory impairment, motor dysfunction, or another medical or neurological condition and are not better explained by intellectual disability (intellectual developmental disorder) or global developmental delay.
Speech Sound Disorder	A. Persistent difficulty with speech sound production that interferes with speech intelligibility or prevents verbal communication of messages. B. The disturbance causes limitations in effective communication that interfere with social participation, academic achievement, or occupational performance, individually or in any combination. C. Onset of symptoms is in the early developmental period. D. The difficulties are not attributable to congenital or acquired conditions, such as cerebral palsy, cleft palate, deafness or hearing loss, traumatic brain injury, or other medical or neurological conditions.
Social (Pragmatic) Communication Disorder	A. Persistent difficulties in the social use of verbal and nonverbal communication as manifested by all of the following: 1. Deficits in using communication for social purposes, such as greeting and sharing information, in a manner that is appropriate for the social context. 2. Impairment of the ability to change communication to match context or the needs of the listener, such as speaking differently in a classroom than on a playground, talking differently to a child than to an adult, and avoiding use of overly formal language. 3. Difficulties following rules for conversation and storytelling, such as taking turns in conversation, rephrasing when misunderstood, and knowing how to use verbal and nonverbal signals to regulate interaction. 4. Difficulties understanding what is not explicitly stated (e.g., making inferences) and nonliteral or ambiguous meanings of language (e.g., idioms, humor, metaphors, multiple meanings that depend on the context for interpretation). B. The deficits result in functional limitations in effective communication, social participation, social relationships, academic achievement, or occupational performance, individually or in combination. C. The onset of the symptoms is in the early developmental period (but deficits may not become fully manifest until social communication demands exceed limited capacities). D. The symptoms are not attributable to another medical or neurological condition or to low abilities in the domains of word structure and grammar, and are not better explained by autism spectrum disorder, intellectual disability (intellectual developmental disorder), global developmental delay, or another mental disorder.

brain, Williams syndrome, and nonverbal learning disabilities. SPCD can also occur independently of other disorders. In school settings, children with SPCD may be socially ostracized and/or bullied.

Intellectual Disability

Most children with a mild degree of intellectual disability learn to talk at a slower-than-normal rate; they follow a normal sequence of language acquisition and eventually master basic communication skills. Difficulties may be encountered with higher-level language concepts and use. Persons with moderate to severe degrees of intellectual disability can have great difficulty in acquiring basic communication skills. About half of persons with an IQ of <50 are able to communicate using single words or simple phrases; the rest are typically nonverbal.

Autism and Pervasive Developmental Disorders

A disordered pattern of language development is one of the core features of autism and other pervasive developmental disorders (see Chapter 28). The language profile of children with autism is often indistinguishable from that in children with SLIs. The key points of distinction between these conditions are the lack of reciprocal social relationships that characterizes children with autism, limitation in the ability to develop functional, symbolic, or pretend play, and an obsessive need for sameness and resistance to change. Approximately 75-80% of children with autism are also intellectually disabled, and this can limit their ability to develop functional communication skills.

Language abilities can range from absent to grammatically intact, but with limited pragmatic features and/or odd prosody patterns. Some autistic persons have highly specialized, but isolated, "savant" skills, such as calendar calculations and hyperlexia (the precocious ability to recognize written words beyond expectation based on general intellectual ability). Regression in language and social skills (**autistic regression**) occurs in approximately one-third of children with autism, usually before 2 yr of age. No explanation for this phenomenon has been identified. Once the regression has "stabilized," recovery of function does not usually occur (Fig. 35-1).

Asperger Syndrome

(See Chapter 28.2.)

Although sharing many characteristics of autism (deficits in social relatedness and restricted range of interests), individuals with Asperger syndrome typically show normal early language development (syntax and semantics). As they mature, higher-order social and language pragmatic impairments become prominent features of this disorder. Affected children have an unusually circumscribed range of interests, which are all-absorbing and interfere with learning of other skills and with social adaptation. These children may engage in long-winded, verbose monologues about their topics of special interest, with little regard to the reaction of others. Their inflection pattern (prosody) may be inappropriate to the content of their conversation, and they might not adjust their rate of speech or vocal volume to the setting.

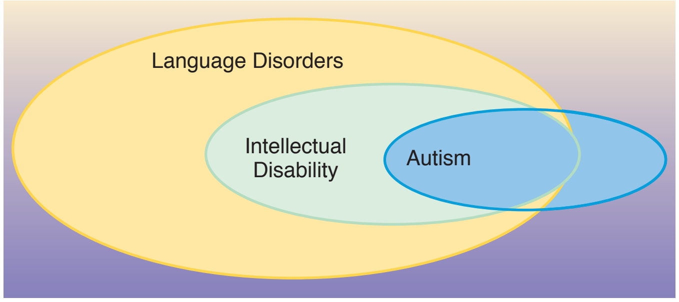

Figure 35-1 Relationship of autism, language disorders, and intellectual disability. *(From Simms MD, Schum RL: Preschool children who have atypical patterns of development,* Pediatr Rev *21:147–158, 2000.)*

Selective Mutism

Selective mutism is defined as a failure to speak in specific social situations despite speaking in other situations, and it is typically a symptom of an underlying **anxiety disorder**. Children with selective mutism can speak normally in certain settings, such as within their home or when they are alone with their parents. They fail to speak in other social settings, such as at school or at other places outside their home. Other symptoms associated with selective mutism can include excessive shyness, withdrawal, dependency on parents, and oppositional behavior. Most cases of selective mutism are not the result of a single traumatic event, but rather are the manifestation of a chronic pattern of anxiety. Mutism is not passive–aggressive behavior. Mute children report that they want to speak in social settings but are afraid to do so. It is important to emphasize that the underlying anxiety disorder is the likely origin of selective mutism. Often, one or both parents of a child with selective mutism has a history of anxiety symptoms, including childhood shyness, social anxiety, or panic attacks. This suggests that the child's anxiety represents a familial trait. For some unknown reason, the child converts the anxiety into the mute symptom. Mutism is highly functional for the child in that it reduces anxiety and protects the child from the perceived challenge of social interaction. Treatment of selective mutism should focus on reducing the general anxiety, rather than focusing only on the mute behaviors (see Chapter 25). Selective mutism reflects a difficulty of social interaction and not a disorder of language processing.

Isolated Expressive Language Disorder

More commonly seen in boys than girls, isolated expressive language disorder (late talker syndrome) is a diagnosis best made in retrospect. These children have age-appropriate receptive language and social ability. Once they start talking, their speech is clear. There is no increased risk for language or learning disability as they progress through school. A family history of other males with a similar developmental pattern is often reported. This pattern of language development likely reflects a variation of normal.

MOTOR SPEECH DISORDERS

Dysarthria

Motor speech disorders can originate from neuromotor disorders such as cerebral palsy, muscular dystrophy, myopathy, facial palsy. The resulting dysarthria affects both speech and nonspeech functions (smiling and chewing). Lack of strength and muscular control manifests as slurring of words and distorting of vowels. Speech patterns are often slow and labored. Poor velopharyngeal function can result in mixed nasal resonance (hyper- or hyponasal speech). In many cases, feeding difficulty, drooling, open mouth posture, and a protruding tongue accompany the dysarthric speech.

Childhood Apraxia of Speech

Difficulty in planning and coordinating movements for speech production can result in inconsistent distortion of speech sounds. The same word may be pronounced differently each time. Intelligibility tends to decline as the length and complexity of the child's speech increases. Consonants may be deleted and sounds transposed. As they try to talk spontaneously, or imitate other's speech, children with childhood apraxia of speech may display oral groping or struggling behaviors. Children with childhood apraxia of speech frequently have a history of early feeding difficulty, limited sound production as infants, and delayed onset of spoken words. They may point, grunt, or develop an elaborate gestural communication system in an attempt to overcome their verbal difficulty. Apraxia may be limited to oral-motor function, or it may be a more generalized problem affecting fine and/or gross motor coordination.

Phonologic Disorder

Children with phonologic speech disorder are often unintelligible, even to their parents. Articulation errors are not the result of neuromotor impairment but seem to reflect an inability to correctly process the words they hear. As a result, they lack understanding of how to fit sounds together properly to create words. In contrast to children with childhood apraxia of speech, those with phonologic disorder are fluent—although unintelligible—and produce a consistent, highly predictable pattern of articulation errors. Children with phonologic speech disorder are at high risk for later reading and learning disability.

HEARING IMPAIRMENT

Hearing loss can be a major cause of delayed or disordered language development (see Chapter 637). Approximately 16-30 per 1,000 children have mild to severe hearing loss, significant enough to affect educational progress. In addition to these "hard of hearing" children, approximately another 1 per 1,000 are deaf (profound bilateral hearing loss). Hearing loss can be present at birth or acquired postnatally. Newborn screening programs can identify many forms of congenital hearing loss, but children can develop progressive hearing loss or acquire deafness after birth.

The most common types of hearing loss are attributable to conductive (middle ear) or sensorineural deficit. Although it is not possible to accurately predict the impact of hearing loss on a child's language development, the type and degree of hearing loss, the age of onset, and the duration of the auditory impairment clearly play important roles. Children with significant hearing impairment often have problems developing facility with language and often have related academic difficulties. Presumably, the language impairment is caused by lack of exposure to fluent language models starting in infancy.

Approximately 30% of hearing-impaired children have at least one other disability that affects development of speech and language (e.g., intellectual disability, cerebral palsy, craniofacial anomalies). Any child who shows developmental warning signs of a speech or language problem should have a hearing assessment by an audiologist and an examination by a geneticist as part of a comprehensive evaluation.

HYDROCEPHALUS

Some children with hydrocephalus may be described as having "cocktail-party syndrome." Although they may use sophisticated words, their comprehension of abstract concepts is limited, and their pragmatic conversational skills are weak. As a result, they speak superficially about topics and appear to be carrying on a monologue (see Chapter 591.11).

RARE CAUSES OF LANGUAGE IMPAIRMENT

Hyperlexia

Hyperlexia is the precocious development of reading single words that spontaneously occurs in some young children (ages 2-5 yr) without specific instruction. It is often associated with children who have a pervasive developmental disorder (see Chapter 30) or SLI. It stands in contrast to precocious reading development in young children who do not have any other developmental disorders. Hyperlexia is a variation seen in young children with disordered language who do not have the social deficits or restricted or repetitive behaviors associated with autism. A typical manifestation is for a child with SLI to orally read single words, or match pictures with single words. Although hyperlexic children show early and well-developed word-decoding skills, they

usually have no precocious ability for comprehension of text. Rather, text comprehension is closely intertwined with oral comprehension, and children who have difficulty decoding the syntax of language are also at risk for having reading comprehension problems.

Landau-Kleffner Syndrome (Verbal Auditory Agnosia)

Children with Landau-Kleffner syndrome have a history of normal language development until they experience a regression in their ability to comprehend spoken language (verbal auditory agnosia). The regression may be sudden or gradual, and it usually occurs between 3 and 7 yr of age. Expressive language skills typically deteriorate, and some children may become mute. Despite their language regression, these children typically retain appropriate play patterns and the ability to interact in a socially appropriate manner. An EEG might show a distinct pattern of status epilepticus in sleep (continuous spike wave in slow-wave sleep), and up to 80% of children with this condition eventually exhibit clinical seizures. A number of treatment approaches have been reported, including antiepileptic medication, steroids, and intravenous gamma globulin, with varying results. The prognosis for return of normal language ability is uncertain, even with resolution of the EEG abnormality. Epileptic interictal discharges are more frequently found on EEGs of children with language impairments than in otherwise normally developing children, even in those without any history of language regression. However, this phenomenon is believed to represent a manifestation of an underlying disorder of brain structure or function that is distinct from the language impairment, as there has been little evidence of improvement in language function when the EEG was normalized after administration of antiepileptic medication. Unless there is a clear pattern of either seizure symptoms or regression in language ability, a routine EEG is not recommended as part of the evaluation for a child with speech and/or language impairment.

Metabolic and Neurodegenerative Disorders

(See also Part XI.)

Regression of language development may accompany loss of neuromotor function at the outset of a number of metabolic diseases including lysosomal storage disorders (metachromatic leukodystrophy), peroxisomal disorders (adrenal leukodystrophy), ceroid lipofuscinosis (Batten disease), and mucopolysaccharidosis (Hunter disease, Hurler disease). Recently, creatine transporter deficiency was identified as an X-linked disorder that manifests with language delay in boys and mild learning disability in female carriers.

Screening

Developmental surveillance at each well child visit should include specific questions about normal language developmental milestones and observations of the child's behavior. Clinical judgment, defined as eliciting and responding to parents' concerns, can detect the majority of children with speech and language problems. Many clinicians employ standardized developmental screening questionnaires and observation checklists designed for use in a pediatrics office (see Chapter 14).

The U.S. Preventive Services Task Force reviewed screening instruments for speech and language delays in young children that can be used in primary care settings. The Task Force focused on brief measures that require <10 min to complete. There was insufficient evidence that screening instruments are more effective than using physician's clinical observations and parents' concerns to identify children who require further evaluation. The Task Force noted that there is no single gold standard for screening, owing to inconsistent measures and terminology, and did not recommend the use of screening instruments. Furthermore, the Task Force determined that the use of formal measures was not time or cost efficient and deferred to pediatrician's and parents' concerns as indicators of potential problems. Table 35-3 offers guidelines for raising concerns and referring a child for specialized speech and language evaluation. Because of the high prevalence of speech and language disorders in the general population, referral to a speech-language pathologist for further evaluation should be made whenever there is a suspicion of delay.

NONCAUSES OF LANGUAGE DELAY

Twinning, birth order, "laziness," exposure to multiple languages (bilingualism), tongue-tie, or otitis media are not adequate explanations for significant language delay. Normal twins learn to talk at the same age as normal single-born children, and birth order effects on language development have not been consistently found. The drive to communicate and the rewards for successful verbal interaction are so strong that children who let others talk for them usually can't talk for themselves and are not "lazy." Toddlers exposed to more than 1 language can show a mild delay in starting to talk, and they can initially mix elements (vocabulary and syntax) of the different languages they are learning (code switching). However, they learn to segregate each language by 24-30 mo and are equal to their monolingual peers by 3 yr of age. An extremely tight lingual frenulum (tongue-tie) can affect feeding and speech articulation, but does not prevent the acquisition of language abilities. Finally, prospective studies show that frequent ear infections and/or serous otitis media in early childhood does not result in persisting language disorder.

Diagnostic Evaluation

It is important to distinguish developmental delay (abnormal timing) from developmental disorder (abnormal patterns or sequences). A child's language and communication skills must also be interpreted within the context of the child's overall cognitive and physical abilities. Finally, it is important to evaluate the child's use of language to communicate with others in the broadest sense (communicative intent). Thus, a multidisciplinary evaluation is often warranted. At a minimum this should include psychologic evaluation, neurodevelopmental pediatric assessment, and speech and language examination.

Psychologic Evaluation

There are 2 main goals for the psychologic evaluation of a young child with a communication disorder. Nonverbal cognitive ability must be assessed to determine if the child has an intellectually disability, and the child's social behaviors must be assessed to determine whether

Table 35-3 Speech and Language Screening

REFER FOR SPEECH–LANGUAGE EVALUATION IF:		
AT AGE	**RECEPTIVE**	**EXPRESSIVE**
15 mo	Does not look/point at 5-10 objects	Is not using 3 words
18 mo	Does not follow simple directions ("get your shoes")	Is not using Mama, Dad, or other names
24 mo	Does not point to pictures or body parts when they are named	Is not using 25 words
30 mo	Does not verbally respond or nod/shake head to questions	Is not using unique 2-word phrases, including noun–verb combinations
36 mo	Does not understand prepositions or action words; does not follow 2-step directions	Has a vocabulary of <200 words; does not ask for things; echolalia to questions; language regression after attaining 2-word phrases

autism spectrum disorder (ASD) is present. Additional diagnostic considerations may include emotional disorders such as anxiety, depression, mood disorder, obsessive-compulsive disorder, academic learning disorders, and attention-deficit/hyperactivity disorder (ADHD).

Cognitive Assessment

Intellectual disability is defined as deficits in cognitive abilities and adaptive behaviors. In this context, children with intellectual disability show delayed development of communication skills; however, delayed communication does not necessarily signal intellectual disability. Therefore, a broad-based cognitive assessment is an important component to the evaluation of children with language delays, including evaluation of both verbal and nonverbal skills. If a child has intellectual disability, both verbal and nonverbal scores will be low compared to norms (≤2nd percentile). In contrast, a typical cognitive profile for a child with SLI includes a significant difference between nonverbal and verbal abilities, with nonverbal IQ being greater than verbal IQ and the nonverbal score within an average range.

Evaluation of Social Behaviors

Social interest is the key difference between children with a primary language disorder (SLI) and those with a communication disorder secondary to ASD. Children with SLI have an interest in social interaction, but they may have difficulty enacting their interest because of their limitations to communication. In contrast, autistic children show little social interest. Four key nonverbal behaviors that are often shown by children with SLI—but not autistic children (especially toddlers and preschoolers)—are joint attention, affective reciprocity, pretend play, and direct imitation.

Relationship of Language and Social Behaviors to Mental Age

Cognitive assessment provides a mental age for the child, and the child's behavior must be evaluated in that context. Most 4 yr old children typically engage peers in interactive play, but most 2 yr olds are playful but primarily focused on interactions with adult caretakers. A 4 yr old with mild to moderate intellectual disability and a mental age of 2 yr might not play with peers yet because of cognitive limitation, not a lack of desire for social interaction.

Speech and Language Evaluation

A certified speech-language pathologist should perform a speech and language evaluation. A typical evaluation includes assessment of language, speech, and the physical mechanisms associated with speech production. Both expressive and receptive language is assessed by a combination of standardized measures and informal interactions and observations. All components of language are assessed, including syntax, semantics, pragmatics, and fluency. Speech assessment similarly uses a combination of standardized measures and informal observations. Assessment of physical structures includes oral structures and function, respiratory function, and vocal quality. In many settings, a speech-language pathologist works in conjunction with an audiologist, who can do appropriate hearing evaluation of the child. If an audiologist is not available in that setting, then a separate referral should be made. No child is too young for a speech and language or hearing evaluation. A referral for evaluation is appropriate whenever there is suspicion of language impairment.

Medical Evaluation

As in any developmental disorder, careful history and physical examination should focus on the identification of potential contributors to the child's language and communication difficulties. A family history of delay in talking, need for speech and language therapy, or academic difficulty can suggest a genetic predisposition to language disorders. Pregnancy history might reveal risk factors for prenatal developmental anomalies, such as polyhydramnios or decreased fetal movement patterns. Small size for gestational age at birth, symptoms of neonatal encephalopathy, or early and persistent oral-motor feeding difficulty may presage speech and language difficulty. Developmental history should focus on the age at which various language skills were mastered and the sequences and patterns of milestone acquisition. Regression or loss of acquired skills should raise immediate concern.

Physical examination should include measurement of height (length), weight, and head circumference. The skin should be examined for lesions consistent with phakomatosis (e.g., tuberous sclerosis, neurofibromatosis, Sturge-Weber syndrome) and other disruptions of pigment (hypomelanosis of Ito). Anomalies of the head and neck, such as white forelock and hypertelorism (Waardenburg syndrome), ear malformations (Goldenhar syndrome), facial and cardiac anomalies (Williams syndrome, velocardiofacial syndrome), retrognathism of the chin (Pierre-Robin anomaly), or cleft lip and/or palate, are associated with hearing and speech abnormalities. Neurologic examination might reveal muscular hypertonia or hypotonia, both of which can affect neuromuscular control of speech. Generalized muscular hypotonia, with increased range of motion of the joints, is commonly seen in children with SLI. The reason for this association is not clear but it might account for the fine and gross motor clumsiness often seen in these children. However, mild hypotonia is not a sufficient explanation for the impairments of expressive and receptive language.

No routine diagnostic studies are indicated for SLI or isolated language disorders. When language delay is a part of a generalized cognitive or physical disorder, referral for further genetic evaluation, chromosome testing (including high resolution banding karyotype, fragile X testing, and microarray comparative genomic hybridization), neuroimaging studies, and EEG may be considered, if clinically indicated.

TREATMENT

Laws emanating from the federal Individuals with Disabilities Education Act (IDEA) require that schools provide special education services to children who have learning difficulties. This includes children with speech and language disorders. Services are provided to children from birth through 21 yr of age. States have various methods for providing services, and for young children these can include Birth-to-Three, Early Childhood, and Early Learning programs. These programs provide speech–language therapy as part of public education, in conjunction with other special education resources. Children can also receive therapy from nonprofit service agencies, hospital and rehabilitation centers, and speech pathologists in private practice.

Of concern is the fact that many children with identified speech and language deficits do not receive appropriate intervention services. Population-based surveys in both the United States and Canada have found that less than half of children identified by kindergarten entry receive speech and language interventions, even when their parents have been educated about the nature of their child's condition. In one study, children with deficits in speech–sound production were much more likely to receive services (41%) than those who had problems with language alone (9%). These findings are troubling because poor educational outcome, especially in reading, social and behavioral adjustment, are more highly associated with language than with speech–sound disorders. Therefore, the children at greatest risk are least likely to receive intervention services. Boys were twice as likely to receive speech intervention as girls, regardless of their speech–language diagnosis. Social and demographic factors did not appear to influence whether identified children received interventions services.

Speech–language therapy includes a variety of goals. Sometimes both speech and language activities are incorporated in therapy. The speech goals focus on development of more intelligible speech. Language goals can focus on expanding vocabulary (lexicon) and understanding of the meaning of words (semantics), improving syntax by using proper forms or learning to expand single words into sentences, and social use of language (pragmatics). Therapy can include individual sessions, group sessions, and mainstream classroom integration. Individual sessions may use drill activities for older children or play activities for younger children to target specific goals. Group sessions can include several children with similar language goals to help them practice peer communication activities and to help them bridge the gap into more naturalistic communication situations. Classroom

integration might include the therapist team-teaching or consulting with the teacher to facilitate the child's use of language in common academic situations.

For children with severe language impairment, alternative methods of communication are often included in therapy. These may include use of manual sign language, use of pictures (e.g., Picture Exchange Communication System), and computerized devices for speech output. Often the ultimate goal is to achieve better spoken language. Early use of signs or pictures can help the child to establish better functional communication and help the child to understand the symbolic nature of words to facilitate the language process. There is no evidence that use of signs or pictures interferes with development of oral language if the child has the capacity to speak. Many clinicians believe that these alternative methods accelerate the learning of language. They also reduce frustration of parents and children who cannot communicate for basic needs.

Parents can consult with their child's speech-language therapist about home activities to enhance language development and extend therapy activities through appropriate language-stimulating activities and recreational reading. Parents' language activities should focus on emerging communication skills that are within the child's repertoire, rather than teaching the child new skills. The speech pathologist can guide parents on effective modeling and eliciting communication from their child.

Recreational reading focuses on expanding the child's comprehension of language. Sometimes the child's avoidance of reading is a sign that the parent is presenting material that is too complex for the child. The speech-language therapist can guide the parent in selecting an appropriate level of reading material.

PROGNOSIS

Children with isolated expressive language disorder ("late talkers") have an excellent prognosis for both language, learning, and social–emotional adjustment.

Over time, children with SLI respond to therapeutic/educational interventions and show a trend toward improvement of communication skills. Adults with a history of childhood language disorder continue to show evidence of impaired language ability, even when surface features of the communication difficulty have improved considerably. This suggests that many persons find successful ways of adapting to their impairment. Although the majority of children improve their communication ability with time, 50-80% of preschoolers with language delay and normal nonverbal intelligence continue to experience difficulty with language and social development up to 20 yr beyond the initial diagnosis. Language disorders often interfere with the child's ability to conceptualize the increasingly complex and ambiguous worlds of social relationship and emotions. As a consequence, in later childhood and adolescence, children with persisting symptoms of SLI are about twice as likely as their typical language peers to show clinical levels of emotional problems and twice as likely to show behavioral difficulties. A Danish study found that adults with SLI were less likely to have completed formal education beyond high school and to have lower occupational and socioeconomic success than the general population. Fifty-six percent held a paid job (vs 84% of the same age general population), of which 35% were unskilled and 40% were skilled workers. Eighty percent of the adults reported having had difficulty reading while in school and most had received remedial teaching, and 50% continued to report reading difficulty as adults (compared with 5% of Danish adults). Lower non-verbal intelligence and comorbid psychiatric and/or neurologic disorders independently contributed to a worse prognosis. These results were consistent with previous reports of adult outcomes of children with SLI from Canada and the United Kingdom.

Academic Disorders

Early language difficulty is strongly related to later reading disorder. Approximately 50% of children with early language difficulty develop reading disorder, and 55% of children with reading disorder have a history of impaired early oral language development. By the time they enter kindergarten, many children with early language deficits may have improved significantly, and they may begin to show early literacy skills, identifying and sounding out letters. However, as they progress through school, they are often unable to keep up with the increasing demands for both oral and written language. Despite their ability to read words, these children lack oral and reading comprehension and struggle with a wide range of academic subjects. This "illusory recovery" of early language skill may result in children losing speech–language services or other special education support in early grades only to be identified later with academic problems. In addition, children with subtle, but persisting language impairments may appear inattentive or anxious in language-rich classroom environments and be misdiagnosed as having an attention disorder.

A study from Australia found that at 7-9 yr of age, children with communication impairments were reported by their parents and teachers to be making slower progress in reading, writing, and overall school achievement than other children their age. The children reported a higher incidence of bullying, poorer peer relationships, and less overall enjoyment of school than their typically developing peers.

COMORBID DISORDERS

Emotional and Behavioral Difficulty

Early language disorder, particularly difficulty with auditory comprehension, appears to be a specific risk factor for later emotional dysfunction. Boys and girls with language disorder have a higher than expected rate of anxiety disorder (principally social phobia). Boys with language disorder are more likely to develop symptoms of ADHD, conduct disorder, and antisocial personality disorder compared with normally developing peers. Language disorders are common in children referred for psychiatric services, but they are often underdiagnosed, and their impact on children's behavior and emotional development is often overlooked.

Preschoolers with language difficulty commonly express their frustration through anxious, socially withdrawn, or aggressive behavior. As their ability to communicate improves, parallel improvements are usually noted in their behavior, suggesting a cause-and-effect relationship between language and behavior. However, the persistence of emotional and behavioral problems over the life span of persons with early language disability suggests a strong biologic or genetic connection between language development and subsequent emotional disorders.

The full impact of environmental and education support on these emotional and behavioral difficulties is not known at this time, but many children with SLI need psychologic support. Efforts should be made to support the child's resilience, emotional competency, and coping abilities. Parents and teachers should be encouraged to strengthen the child's prosocial behavior and to reduce noncompliant and aggressive behaviors.

Motor and Coordination Delays

Approximately one-third to one-half of children with speech and/or language disorders have some degree of motor coordination impairment that may have an important impact on their ability to carry out activities of daily living (dressing, eating, and bathing), school tasks (writing, drawing, coloring), and social/recreational activities (participation in sports and other playground activities). Motor difficulties are not related to the type of language impairment (i.e., they are found in both children with only receptive delays and in those with both expressive and receptive delays). The patterns of motor difficulties seen in children with language impairments are not distinctly "abnormal" and the motor profiles of children with language impairments resemble those of younger children, suggesting that they result from delayed maturation of motor development rather than from a neurologic impairment. Several researchers have postulated that language impairments and motor difficulties may have a common neurodevelopmental basis. Because attention may be focused on the child's language delays, the need for intervention and support for the child's comorbid motor impairment may be overlooked.

35.1 Childhood-Onset Fluency Disorder: Dysfluency (Stuttering, Stammering)

Kenneth L. Grizzle

Fluent speech requires timely synchronization of phonatory and articulatory muscle groups. There is also an important interaction between speech and language skills. Stuttering involves involuntary frequent repetitions, lengthenings (prolongations) or arrests (blocks, pauses) of syllables, or sounds that are exacerbated by emotionally or syntactically demanding speech. The World Health Organization's definition of *stuttering* is a disorder in the rhythm of speech in which the person knows precisely what he or she wishes to say but at the same time may have difficulty saying it because of an involuntary repetition, prolongation, or cessation of sound. Table 35-4 describes the DSM-5 definition. Stuttering often leads to frustration and avoidance of speaking situations. Stuttering can lead to being bullied or teased and to speech-related anxiety and social phobia.

EPIDEMIOLOGY AND ETIOLOGY

Stuttering usually begins at 2-4 yr of age and is seen more often in boys (4 : 1). Approximately 3-5% of preschool children stutter to some degree; only 0.7-1% of young adults stutter. Stuttering is common in families. Genetic studies suggest genes located on chromosome 12. Stuttering may occur suddenly and often begins when word combinations are involved. Higher vocabulary at age 2 yr and higher material education may also be associated with stuttering. Girls and those with a family history of recovery are most likely to have spontaneous recovery by adolescence. This recovery is not related to the severity of the stuttering. Approximately 75% of boys stop stuttering by adolescence; approximately 90% of girls stop by adolescence.

Adolescent/young adult onset stuttering may be related to central nervous system pathology. In contrast to childhood onset, adolescents may have dysfluency with each word whereas childhood onset usually manifests stuttering on the first word or syllable of a phrase.

Stuttering may be caused by impaired timing between areas of the brain involved in language preparation and execution. Adults who stutter and those with fluent speech activate similar areas of the brain. In addition, adults who stutter overactivate parts of the motor cortex and cerebellar vermis, show right-sided laterality, and have no auditory activation on hearing their own speech.

DIAGNOSIS

Stuttering must be differentiated from the normal developmental dysfluency of preschool children (Tables 35-5 and 35-6). Developmental dysfluency is characterized by brief periods of stuttering that resolve by school age, and it usually involves whole words, with <10 dysfluencies per 100 words. Table 35-4 lists the DSM-5 diagnostic criteria for stuttering. Stuttering often improves while singing, reading aloud, or talking to pets or toys. It increases in intensity with anxiety-inducing situations such as reading or speaking in public or on the phone. Some children who stutter develop behavior routines such as eye blinking, grimacing, head turning, and arm or neck movements. Stuttering that persists and is associated with tics may be a manifestation of **Tourette syndrome** (see Chapters 24.1 and 597.4). Additional disorders in the

Table 35-4 Childhood-Onset Fluency Disorder (Stuttering)

Diagnostic Criteria

A. Disturbances in the normal fluency and time patterning of speech that are inappropriate for the individual's age and language skills, persist over time, and are characterized by frequent and marked occurrences of one (or more) of the following:
   1. Sound and syllable repetitions.
   2. Sound prolongations of consonants as well as vowels.
   3. Broken words (e.g., pauses within a word).
   4. Audible or silent blocking (filled or unfilled pauses in speech).
   5. Circumlocutions (word substitutions to avoid problematic words).
   6. Words produced with an excess of physical tension.
   7. Monosyllabic whole-word repetitions (e.g., "I-I-I-I see him").

B. The disturbance causes anxiety about speaking or limitations in effective communication, social participation, or academic or occupational performance, individually or in any combination.

C. The onset of symptoms is in the early developmental period. (Note: Later-onset cases are diagnosed as 307.0 [F98.5] adult-onset fluency disorder.)

D. The disturbance is not attributable to a speech-motor or sensory deficit, dysfluency associated with neurological insult (e.g., stroke, tumor, trauma), or another medical condition and is not better explained by another mental disorder.

Table 35-5 Differences Between Stuttering and Developmental Dysfluency

BEHAVIOR	STUTTERING	DEVELOPMENTAL DYSFLUENCY
Frequency of syllable repetition per word	≥2	≤1
Tempo	Faster than normal	Normal
Airflow	Often interrupted	Rarely interrupted
Vocal tension	Often apparent	Absent
Frequency of prolongations per 100 words	≥2	≤1
Duration of prolongation	≥2 sec	≤1 sec
Tension	Often present	Absent
Silent pauses within a word	May be present	Absent
Silent pauses before a speech attempt	Unusually long	Not marked
Silent pauses after the dysfluency	May be present	Absent
Articulating postures	May be inappropriate	Appropriate
Reaction to stress	More broken words	No change in dysfluency
Frustration	May be present	Absent
Eye contact	May waver	Normal

differential diagnosis include hearing impairment, medication effects, cluttering, and in adolescent onset stuttering, central nervous system disorders.

TREATMENT

Preschool children with normal developmental dysfluency (see Table 35-6) can be observed with parental education and reassurance. Parents should not reprimand the child or create undue anxiety. Preschool or older children with stuttering should be referred to a speech pathologist. Therapy is most effective if started during the preschool period. In addition to the risks noted in Table 35-4, indications for referral include 3 or more dysfluencies per 100 syllables (*b-b-but; th-th-the; you, you, you*), avoidances or escapes (pauses, head nod, blinking), discomfort or anxiety while speaking, and suspicion of an associated neurologic or psychotic disorder.

Most preschool children respond to interventions taught by speech pathologists and to behavioral feedback by parents. Parents should not yell at the child, but should calmly praise periods of fluency ("That was smooth") or nonjudgmentally note episodes of stuttering ("That was a bit bumpy"). The child can be involved with self-correction and respond to requests ("Can you say that again?") made by a calm parent. Such treatment greatly improves dysfluency but it may never be completely eliminated.

Adolescents and adults have also been treated (off label) with risperidone or olanzapine with varying but usually positive results if behavioral speech therapy is unsuccessful. Speech therapy in adolescents may be different from that in young children and involves speech restructuring with the development of a new speech pattern.

Chapter 36

Intellectual Disability

Bruce K. Shapiro and Mark L. Batshaw

Intellectual disability refers to a group of disorders that have in common deficits of adaptive and intellectual function and an age of onset before maturity is reached.

DEFINITION

Contemporary conceptualizations of intellectual disability emphasize functioning and social interaction rather than test scores. The definitions of intellectual disability by the World Health Organization International Classification of Diseases, Individuals with Disabilities Education Act (IDEA), the American Psychiatric Association (*Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* [DSM-5]) and the American Association on Intellectual and Developmental Disabilities (AAIDD) all include significant impairment in general intellectual function, social skills, and adaptive behavior. This focus on the conceptual, social, and practical enables the development of individual treatment plans designed to enhance functioning. Consistent across these definitions is onset of symptoms before age 18 yr or adulthood or during childhood, even if the diagnosis is made later in life.

Significant impairment in general intellectual function refers to performance on an individually administered test of intelligence that is approximately 2 SD below the mean. For a test that has a mean of 100 and SD of 15, IQ scores below 70 would meet these criteria. If the standard error of measurement is considered, the upper limits of subaverage intellectual function may extend to an IQ of 75. Using a score of 75 to delineate intellectual disability might double the number of children with intellectual disability, but the requirement for impairment of adaptive skills limits the false positives. Children with intellectual disability often show a variable pattern of strengths and weaknesses. Not all of their partial scores on IQ tests fall into the significantly subaverage range.

Significant impairment in adaptive behavior reflects the degree that the cognitive dysfunction impairs daily function. Adaptive behavior refers to the skills that are required for people to function in their everyday lives. The AAIDD and DSM-5 classifications of adaptive behavior addresses 3 broad sets of skills: conceptual, social, and practical. Conceptual skills include language, reading and writing, money concepts, and self-direction. Social skills include interpersonal skills, personal responsibility, self-esteem, gullibility, naiveté, and ability to follow rules, obey laws, and avoid victimization. Representative practical skills are performance of activities of daily living (dressing, feeding, toileting and bathing, mobility), instrumental activities of daily living (e.g., housework, managing money, taking medication, shopping, preparing meals, using the telephone), occupational skills, and the maintenance of a safe environment. For a deficit in adaptive behavior to be present, a significant delay in 1 of the 3 areas must be present. The rationale for requiring only 1 of the 3 areas is the empirically derived finding that people with intellectual disability can have varying patterns of ability and may not have deficits in all 3 areas.

The requirement for adaptive behavior deficits is the most controversial aspect of the diagnostic formulation. The controversy centers on 2 broad areas: whether impairments in adaptive behavior are necessary for the construct of intellectual disability and what to measure. The adaptive behavior criterion may be irrelevant for many children; adaptive behavior is impaired in virtually all children who have IQ scores <50. The major utility of the adaptive behavior criterion is to confirm intellectual disability in children with IQ scores in the 65-75 range. It should be noted that deficits in adaptive behavior are often found in disorders such as autism spectrum disorders (see Chapter 30) and attention-deficit/hyperactivity disorder (ADHD) (see Chapter 33) in the presence of typical intellectual function.

The issues of measurement are important as well. The independence of the 3 domains of adaptive behavior has not been validated with research. The relationship between adaptive behavior and IQ performance is insufficiently explored. Most adults with mild intellectual disability do not have significant impairments in practical skills. It should be noted that adaptive behavior deficits must be distinguished from maladaptive behavior (e.g., aggression, inappropriate sexual contact).

Onset before age 18 yr or adulthood distinguishes dysfunctions that originate during the developmental period. The diagnosis of intellectual disability may be made after 18 yr of age or childhood, but the cognitive and adaptive dysfunction must have been manifested before age 18 or adulthood (e.g., during "childhood").

The term **mental retardation** should be cast aside because it is stigmatizing, has been used to limit the achievements of the individual, and has not met its initial objective of providing assistance to people with the disorder. The term **intellectual disability** is increasingly used

Table 36-1 Identification of Cause in Children with Severe Intellectual Disability

CAUSE	EXAMPLES	PERCENT OF TOTAL
Chromosomal disorder	Trisomies 21, 18, 13, Deletion 1p36 Klinefelter syndrome Wolf Hirschhorn syndrome	~20
Genetic syndrome	Fragile X syndrome Prader-Willi syndrome Rett syndrome	~20
Nonsyndromic autosomal mutations	Variations in copy number, de novo mutations in *SYNGAP1*, *GRIK2*, *TUSC3*, oligosaccharyl transferase, and others	~10
Developmental brain abnormality	Hydrocephalus ± meningomyelocele, lissencephaly	~8
Inborn errors of metabolism or neurodegenerative disorder	PKU, Tay-Sachs, various storage diseases	~7
Congenital infections	HIV, toxoplasmosis, rubella, CMV, syphilis, herpes simplex	~3
Familial intellectual disability	Environment, syndromic, or genetic	~5
Perinatal causes	HIE, meningitis, IVH, PVL, fetal alcohol syndrome	4
Postnatal causes	Trauma (abuse), meningitis, hypothyroidism	~4
Unknown	Cerebral palsy	20

CMV, Cytomegalovirus; HIE, hypoxic ischemic encephalopathy; HIV, human immunodeficiency virus; IVH, intraventricular hemorrhage; PKU, phenylketonuria; PVL, periventricular leukomalacia.

Modified from Stromme P, Hayberg G: Aetiology in severe and mild mental retardation: a population based study of Norwegian children, Dev Med Child Neurol *42:76–86, 2000.*

in its place, but has not been adopted universally. In the United States, some existing laws and their attendant entitlements still use the term mental retardation. In Europe, the term **learning disability** is often used to describe intellectual disability. **Global developmental delay** is a term often used to describe young children whose limitations have not yet resulted in a formal diagnosis of intellectual disability; it is often inappropriately used beyond the point when it is clear the child has intellectual disability, usually age 3 yr. Developmental delay is a classification that may be used by IDEA until age 9 yr.

ETIOLOGY

There appear to be 2 overlapping populations of children with intellectual disability: mild (IQ 50-70), which is more associated with environmental influences, and severe (IQ <50), which is more frequently linked to biologic and genetic causes. Mild intellectual disability is 4 times more likely to be found in the offspring of women who have not completed high school than in women who have graduated. This is presumably a consequence of both genetic (children can inherit an intellectual impairment) and socioeconomic (poverty, malnutrition) factors. The specific causes of mild intellectual disability are identifiable in <50% of affected individuals. The most common biologic causes of mild intellectual disability include genetic or chromosomal syndromes with multiple, major, or minor congenital anomalies (velocardiofacial syndrome, Williams syndrome, Noonan syndrome), intrauterine growth restriction, prematurity, perinatal insults, intrauterine exposure to drugs of abuse (including alcohol), and sex chromosomal abnormalities. Familial clustering is common.

In children with severe intellectual disability, a biologic cause (most commonly prenatal) can be identified in more than 75% of cases. Causes include chromosomal (e.g., Down syndrome Wolf-Hirschhorn syndrome, deletion 1p36 syndrome) and other genetic and epigenetic disorders (e.g., fragile X syndrome, Rett syndrome, Angelman and Prader-Willi syndromes), abnormalities of brain development (e.g., lissencephaly), and inborn errors of metabolism or neurodegenerative disorders (e.g., mucopolysaccharidoses) (Table 36-1). Nonsyndromic severe intellectual disability may be a result of inherited or de novo gene mutations, as well as microdeletions or microduplications not detected on standard chromosome analysis. More than 400 genes may be associated with nonsyndromic intellectual disability, with many detected by exomic sequencing. These de novo point mutations may also cause other phenotype features such as seizures or autism; the absence of these features suggests more pleotropic manifestations of genetic mutations. Consistent with the finding that disorders that alter early embryogenesis are the most common and severe, the earlier the problem occurs in development, the more severe its consequences tend to be.

EPIDEMIOLOGY

The prevalence of intellectual disability depends on the definition, the method of ascertainment, and the population. According to statistics, 2.5% of the population should have intellectual disability, and 75% of these individuals should fall into the mild to moderate range. Rates vary across populations. Globally, the prevalence of intellectual disability has been estimated to be approximately 16.41/1,000 persons in low income countries, approximately 15.94/1,000 for middle-income countries, and approximately 9.21/1,000 in high-income countries. Overall, intellectual disability occurs more in boys than in girls: 2 : 1 in mild intellectual disability and 1.5 : 1 in severe intellectual disability. In part this may be a consequence of the many X-linked disorders associated with intellectual disability, the most prominent being fragile X syndrome (see Chapter 81.5).

In 2009-2010 in the United States, approximately 463,000 or 0.9% of school-age children received services for intellectual disability in federally supported school programs. For several reasons, fewer children than predicted are identified as having mild intellectual disability. Because it is more difficult to diagnose mild intellectual disability than the more severe forms, professionals might defer the diagnosis and give the benefit of the doubt to the child. Other reasons that contribute to the discrepancy are use of instruments that underidentify young children with mild intellectual disability (Chapter 30), some children being diagnosed as having autism spectrum disorders and their intellectual disability not addressed, and a disinclination to make the diagnosis in poor or minority students because of previous overdiagnosis.

Young children might show cognitive limitations without significant delays in adaptive behavior. As a result, new cases of mild intellectual disability continue to be diagnosed among children up to 9 yr of age. Children with intellectual disability also may be incorporated into another diagnosis (e.g., autism, cerebral palsy). Furthermore, it

is possible that the number of children with mild intellectual disability is actually decreasing as a result of public health and education measures to prevent prematurity and provide early intervention and head start programs. In fact, the number of school children who receive services for intellectual disability has decreased since 1999, but if developmental delay is included, the numbers have not changed appreciably.

Unlike mild intellectual disability, where the prevalence may be decreasing, the occurrence of severe intellectual disability has not changed appreciably since the 1940s and is 0.3-0.5% of the population. Many of the causes of severe intellectual disability involve genetic or congenital brain malformations that can neither be anticipated nor treated at present. In addition, new populations with severe intellectual disability have offset the decreases in the prevalence of severe intellectual disability that have resulted from improved healthcare. Although prenatal diagnosis and subsequent pregnancy terminations have resulted in a decreased prevalence of Down syndrome (see Chapter 81), and newborn screening with early treatment has virtually eliminated intellectual disability caused by phenylketonuria and congenital hypothyroidism, an increased prevalence of maternal prenatal drug use (see Chapter 96.4) and improved survival of very-low birthweight premature infants has counterbalanced this effect.

PATHOLOGY AND PATHOGENESIS

The limitations in our knowledge of the neuropathology of intellectual disability are exemplified by the fact that 10-20% of brains of persons with severe intellectual disability appear entirely normal by standard neuropathologic study. The majority of brains of these persons show only mild, nonspecific changes that correlate poorly with the degree of intellectual disability. These changes include microcephaly, gray matter heterotopias in the subcortical white matter, unusually regular columnar arrangement of the cortex, and neurons that are more tightly packed than usual. Only a minority of the brain shows more specific changes in dendritic and synaptic organization, with dysgenesis of dendritic spines or cortical pyramidal neurons, or impaired growth of dendritic trees. The programming of the central nervous system (CNS) involves a process of induction; CNS maturation is defined in terms of genetic, molecular, autocrine, paracrine, and endocrine influences. Receptors, signaling molecules, and genes are critical to brain development. The maintenance of different neuronal phenotypes in the adult brain involves the same genetic transcripts that play a crucial role during fetal development, with activation of similar intracellular signal transduction mechanisms. Several syndromes that were thought to involve complex chromosomal abnormalities are, in fact, caused by single-gene mutations involving induction. Rubinstein-Taybi syndrome (see Chapter 81), a disorder marked clinically by broad thumbs and great toes, characteristic facies, and severe intellectual disability, results from a mutation in the gene encoding for the transcriptional coactivator CREB-binding protein (CBP), a factor important in the control of gene expression in early embryogenesis.

CLINICAL MANIFESTATIONS

Early diagnosis of intellectual disability facilitates earlier intervention, identification of abilities, realistic goal setting, easing of parental anxiety, and greater acceptance of the child in the community. Most children with intellectual disability first come to the pediatrician's attention in infancy because of dysmorphisms, associated developmental disabilities, or failure to meet age-appropriate developmental milestones. There are no specific physical characteristics of intellectual disability, but dysmorphisms may be the earliest signs that bring children to the attention of the pediatrician. They might fall within a genetic syndrome such as Down syndrome or be isolated, as in microcephaly or failure to thrive. Associated developmental disabilities include seizure disorders, cerebral palsy, hypotonia, and autism; these conditions are seen more commonly in conjunction with intellectual disability than in the general population.

Most children with intellectual disability do not keep up with their peers and fail to meet age-expected norms. In early infancy, failure to meet age-appropriate expectations can include a lack of visual or auditory responsiveness, unusual muscle tone (hypo- or hypertonia) or posture, and feeding difficulties. Between 6 and 18 mo of age, gross motor delay (lack of sitting, crawling, walking) is the most common complaint. Language delay and behavior problems are common concerns after 18 mo (Table 36-2). Earlier identification of atypical development is likely to occur with more severe impairments; and intellectual disability is usually identifiable by age 3 yr.

For some children with mild intellectual disability the diagnosis remains uncertain during the early school years. It is only after the demands of the school setting increase over the years, changing from "learning to read" to "reading to learn," that the child's limitations are clarified.

Adolescents with mild intellectual disability can present a diagnostic challenge. Typically they are up to date on current trends and are conversant as to who, what, and where. It isn't until the "why" and "how" questions are asked that their limitations become apparent. If allowed to interact at a superficial level, their mild intellectual disability might not be appreciated, even by professionals who may be their special education teachers or healthcare providers. Because of the stigma associated with intellectual disability, they may use euphemisms to avoid being thought of as "stupid" or "retarded" and refer to themselves as learning disabled, dyslexic, language disordered, or slow learners. Some people with intellectual disability emulate their social milieu to be accepted. They may be social chameleons and assume the morals of the group to which they are attached. Some would rather be thought "bad" than "incompetent."

LABORATORY FINDINGS

The most commonly used medical diagnostic testing for children with intellectual disability include neuroimaging; metabolic, genetic, and chromosomal testing; microarray analysis; and electroencephalography. These tests should not be used as screening tools for all children with an intellectual disability. In some children, there is a reasonable yield for testing, whereas in others the yield of <1% does not support its use. Decisions on diagnostic testing should be based on the medical and family history, physical examination, testing by other disciplines, and the family's wishes. Table 36-3 summarizes clinical practice guidelines that have been published and the yields of testing to assist in evaluating the child with global developmental delay or intellectual disability. Microarray analysis has replaced karyotyping as the preferred approach for children with multiple anomalies or a positive family history. Microarray analysis has the ability to discern abnormalities that are below the resolution of karyotyping. For example, deletion 1p36 syndrome, the most common subtelomeric microdeletion syndrome (1 : 5,000 births), accounts for approximately 1% of

Table 36-2 Common Presentations of Intellectual Disability By Age

AGE	AREA OF CONCERN
Newborn	Dysmorphic syndromes, (multiple congenital anomalies), microcephaly Major organ system dysfunction (e.g., feeding and breathing)
Early infancy (2-4 mo)	Failure to interact with the environment Concerns about vision and hearing impairments
Later infancy (6-18 mo)	Gross motor delay
Toddlers (2-3 yr)	Language delays or difficulties
Preschool (3-5 yr)	Language difficulties or delays Behavior difficulties, including play Delays in fine motor skills: cutting, coloring, drawing
School age (>5 yr)	Academic underachievement Behavior difficulties (attention, anxiety, mood, conduct, etc.)

children with developmental disabilities and is characterized by failure to thrive, microcephaly, deep-set eyes, midface hypoplasia, broad nasal bridge, heart deficits, and CNS anomalies. Noncompaction cardiomyopathy and seizures are also noted. The diagnosis is made by standard chromosomes in only approximately 20% and requires fluorescent in situ hybridization or microarray comparative genomic hybridization methods for remaining patients. Microarray analysis may identify variants of unknown significance or benign variants, and therefore should be used in conjunction with a genetic consultation. Karyotyping has a role for children whose array analysis is unrevealing and concern is present for inversions, balanced insertions, and reciprocal translocations. Fluorescent in situ hybridization and subtelomeric analysis have been largely replaced by microarray analysis but continue to be used for specific indications. If microarray analysis is not diagnostic whole exome sequencing increases the diagnostic yield in many children with nonsyndromic severe intellectual disability.

Molecular genetic testing for fragile X syndrome is appropriate for a boy with moderate intellectual disability, unusual physical features, and/or a family history of intellectual disability, or for a girl with more subtle cognitive deficits associated with severe shyness and a relevant family history. For children with a strong history of X-linked intellectual disability, specific testing of genes or the entire chromosome may be revealing. MECP2 (methyl CpG binding protein 2 [Rett syndrome]) testing should be considered in girls with moderate to severe disability.

A child with a progressive neurologic disorder, developmental regression, or acute behavioral changes needs metabolic investigation (urinary organic acids, plasma amino acids, blood lactate, lysosomal enzymes in lymphocytes), although many of these disorders are detectable as part of newborn screening; a child with seizure-like episodes should have an electroencephalography performed. Children with micro- or macrocephaly or changes in head growth trajectory or asymmetric head shapes, as well as those with new or focal neurologic findings, including seizures, should have a neuroimaging procedure.

MRI scans identify a significant number of subtle markers of cerebral dysgenesis in children with intellectual disability. Formes frustes

Table 36-3 Suggested Evaluation of the Child with Intellectual Disability/Global Developmental Delay

TEST	COMMENT
In-depth history	Includes pre-, peri-, and postnatal events (including seizures); developmental attainments; and 3-generation pedigree in family history
Physical examination	Particular attention to minor or subtle abnormalities; neurologic examination for focality and skull abnormalities Behavioral phenotype
Vision and hearing evaluation	Essential to detect and treat; can mask as developmental delay
Gene microarray analysis	A 7.8% yield overall (10% in syndromic and 6.5% in nonsyndromic intellectual disability) Better resolution than Karyotype. May identify up to twice as many abnormalities as karyotyping. Excellent in detecting de novo microdeletions or microduplications
Karyotype	Yield 4% in global developmental delay/intellectual disability Best for inversions and balanced insertions, reciprocal translocations, and polyploidy
Fragile X screen	Combined yield 2% Preselection on clinical grounds can increase yield to 7.6%
X-linked candidate intellectual disability genes	May explain up to 10% of intellectual disability Yield may be as high as 42% if there is a definite family history and as high as 17% from a possibly linked kindred
Exomic gene sequencing	Detects inherited and de novo point mutations especially in nonsyndromic severe intellectual disability
Neuroimaging	MRI preferred. Positives increased by abnormalities of skull contour or microcephaly and macrocephaly, or focal neurologic examination. Overall has a higher yield Identification of specific etiologies is rare. Most conditions that are found do not alter the treatment plan. Need to weigh risk of sedation against possible yield
Thyroid (T_4, TSH)	Near 0% in settings with universal newborn screening program
Serum lead	If there are identifiable risk factors for excessive environmental lead exposure
Metabolic testing	Yield 0.2-4.6% based on clinical indicators and tests performed Urine organic acids, plasma amino acids, ammonia, lactate, and a capillary blood gas. Focused testing based on clinical findings is warranted Tandem mass spectrometry newborn screening has allowed for identification of many disorders in perinatal period and have decreased yield in older children. Other disorders have emerged; e.g., congenital disorders of glycosylation and disorders of creatine synthesis and transport
MECP2 for Rett syndrome	1.5% of females with severe intellectual disability 0.5% of males
EEG	May be deferred in absence of history of seizures
Repeated history and physical examination	Can give time for maturation of physical and behavioral phenotype. New technology may be available for evaluation

EEG, Electroencephalogram; CGH, comparative genomic hybridization; MECP2, methyl CpG binding protein 2; T_4, thyroxine; TSH, thyroid-stimulating hormone.

Based on Michelson DJ, Shevell MI, Sherr EH, et al: Evidence report: Genetic and metabolic testing on children with global developmental delay: report of the Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of Child Neurology. Neurology 77:1629-35, 2011; Curry CJ, Stevenson RE, Aughton D, et al: Evaluation of mental retardation: recommendations of a Consensus Conference: American College of Medical Genetics. Am J Med Genet 12:72:468-477, 1997. Shapiro BK, Batshaw ML: Mental retardation. In Burg FD, Ingelfinger JR, Polin RA, et al: Gellis and Kagan's current pediatric therapy, *ed 18, Philadelphia, 2005, WB Saunders, used with permission; and Shevell M, Ashwal S, Donley D, et al: Practice parameter: evaluation of the child with global developmental delay,* Neurology *60:367–380, 2003.*

of amino acid and organic acid disorders are associated with intellectual disability in the absence of the more commonly associated manifestations of behavior change, lethargy, and coma.

Some children with more subtle physical or neurologic findings can also have determinable biologic causes of their intellectual disability (see Chapter 83). How intensively one investigates the cause of a child's intellectual disability is based on a number of factors:

- What is the degree of intellectual disability? One is less likely to find a biologic cause in a child with mild intellectual disability than in a child with a severe intellectual disability.
- Is there a specific diagnostic path to follow? If there is a medical history or a family history, or if physical findings pointing to a specific disorder, a diagnosis is more likely to be made. In the absence of these indicators, it is difficult to choose specific tests to perform.
- Are the parents planning on having additional children? If so, one would be more likely to intensively seek disorders for which prenatal diagnosis or a specific early treatment option is available.
- What are the parents' wishes? Some parents have little interest in searching for the cause of the intellectual disability and focus exclusively on treatment. Others are so focused on obtaining a diagnosis that they have difficulty following through on interventions until a cause has been found. The entire spectrum of responses must be respected, and supportive guidance should be provided in the context of the parents' education.

DIFFERENTIAL DIAGNOSIS

One of the important roles of pediatricians is the early recognition and diagnosis of cognitive deficits. The developmental surveillance approach to early diagnosis of intellectual disability should be multifaceted. Parents' concerns and observations about their child's development should be listened to carefully, because their observations have been found to be as accurate as developmental screening tests. Medical, genetic, and environmental risk factors should be recognized. Infants at high risk (prematurity, maternal substance abuse, perinatal insult) should be registered in newborn follow-up programs in which they are evaluated periodically for developmental lags in the first 2 yr of life; they should be referred to early intervention programs as appropriate. Developmental milestones should be recorded routinely during healthcare maintenance visits. The American Academy of Pediatrics has formulated a schema for developmental surveillance and screening. Whether developmental surveillance is a more effective technique for identifying than recognizing failure to meet age-appropriate milestones has not been clearly established.

Before making the diagnosis of intellectual disability, other disorders that affect cognitive abilities and adaptive behavior should be considered. These include conditions that mimic intellectual disability and others that involve intellectual disability as an associated impairment. Sensory deficits (severe hearing and vision loss), communication disorders, and poorly controlled seizure disorders can mimic intellectual disability; certain progressive neurologic disorders can appear as intellectual disability before regression is appreciated. More than half of children with cerebral palsy (see Chapter 598) or autism spectrum disorders (see Chapter 30) also have intellectual disability as an associated deficit. Differentiation of isolated **cerebral palsy** from intellectual disability relies on motor skills being more affected than cognitive skills and on the presence of pathologic reflexes and tone changes. In **autism spectrum disorders,** language and social adaptive skills are more affected than nonverbal reasoning skills, whereas in intellectual disability there are usually more equivalent deficits in social, fine motor, adaptive, and cognitive skills.

DIAGNOSTIC PSYCHOLOGIC TESTING

The formal diagnosis of intellectual disability requires the administration of individual tests of intelligence and adaptive functioning.

The Bayley Scales of Infant Development (BSID-III), the most commonly used infant intelligence scale, assesses language, visual problem-solving skills, behavior, fine motor skills, and gross motor skills in children between 1 mo and 42 mo of age. A Mental Developmental Index (MDI) and a Psychomotor Development Index (PDI, a measure of motor competence) score are derived from the results. This test permits the differentiation of infants with severe intellectual disability from typically developing infants, but it is less helpful in distinguishing between a typical child and one with mild intellectual disability.

The most commonly used psychologic tests for children older than 3 yr of age are the Wechsler Scales. The Wechsler Preschool and Primary Scale of Intelligence, 4th edition (WPPSI-IV) is used for children with mental ages of 2.5-7.6 yr. The Wechsler Intelligence Scale for Children, 4th edition (WISC-IV), is used for children who function above a 6 yr mental age. Both scales contain a number of subtests in the areas of verbal and performance skills. Although children with intellectual disability usually score below average on all subscale scores, they occasionally score in the average range in 1 or more performance areas.

The most commonly used test of adaptive behavior is the **Vineland Adaptive Behavior Scale** (VABS), which involves semi structured interviews with parents and/or caregivers and teachers that assess adaptive behavior in four domains: communication, daily living skills, socialization, and motor skills. Other tests of adaptive behavior include the Woodcock-Johnson Scales of Independent Behavior–Revised, the American Association on Intellectual and Developmental Disability Adaptive Behavior Scale (ABS-2nd edition), and the Adaptive Behavior Assessment System (ABAS-2nd edition). There is usually (but not always) a good correlation between scores on the intelligence and adaptive scales. Basic adaptive abilities (feeding, dressing, hygiene) are more responsive to remedial efforts than is the IQ score. Adaptive abilities are also more variable, which can relate to the underlying condition and to environmental expectations. Although persons with Prader-Willi syndrome (see Chapter 81) have stability of adaptive skills through adulthood, those with fragile X syndrome may have increasing deficits over time.

COMPLICATIONS

Children with intellectual disability have higher rates of vision, hearing, neurologic, orthopedic, and behavioral or emotional disorders than do typically developing children. These other problems are often detected later in children with intellectual disability. If untreated, the associated impairments can potentially adversely affect the individual's outcome more than the intellectual disability itself.

The most common associated deficits are motor impairments, behavioral and emotional disorders, medical complications, and seizures. The more severe the intellectual disability, the greater are the number and severity of associated impairments. Knowing the cause of the intellectual disability can help predict which associated impairments are most likely to occur. Fragile X syndrome and fetal alcohol syndrome (see Chapter 106.2) are associated with a high rate of behavioral disorders; Down syndrome has many medical complications (hypothyroidism, celiac disease, congenital heart disease, atlantoaxial subluxation). Associated impairments can require ongoing physical therapy, occupational therapy, speech-language therapy, adaptive equipment, glasses, hearing aids, and medication. Failure to identify and treat these impairments adequately can hinder successful habilitation and result in difficulties in the school, home, and/or neighborhood environment.

PREVENTION

Examples of primary programs to prevent intellectual disability include:

- Increasing the public's awareness of the adverse effects of alcohol and other drugs of abuse on the fetus
- Preventing teen pregnancy and promoting early prenatal care
- Preventing traumatic injury by encouraging the use of guards and railings to prevent falls and other avoidable injuries in the home; using appropriate seat restraints when driving and wearing a safety helmet when biking or skateboarding; teaching firearms safety
- Preventing poisonings by teaching parents about locking up medications and potential poisons

- Encouraging safe sexual practices to prevent the transmission of diseases
- Implementing immunization programs to reduce the risk of intellectual disability caused by encephalitis, meningitis, and congenital infection

Presymptomatic detection of certain disorders can result in treatment that prevents adverse consequences. State newborn screening by tandem mass spectrometry (now including >50 rare genetic disorders in most states), newborn hearing screening, and preschool lead poisoning prevention programs are examples. Thyroid screening in a child with Down syndrome is an example of presymptomatic testing in a disorder associated with intellectual disability.

TREATMENT

Although intellectual disability is not treatable, many associated impairments are amenable to intervention and therefore benefit from early identification. Most children with an intellectual disability do not have a behavioral or emotional disorder as an associated impairment, but challenging behaviors (aggression, self-injury, oppositional defiant behavior) and mental illness (mood and anxiety disorders) occur with greater frequency in this population than among children with typical intelligence. These behavioral and emotional disorders are the primary cause for out-of-home placements, reduced employment prospects, and decreased opportunities for social integration. Some behavioral and emotional disorders are difficult to diagnose in children with more severe intellectual disability because of the child's limited abilities to understand, communicate, interpret, or generalize. Other disorders are masked by the intellectual disability. The detection of ADHD (see Chapter 33) in the presence of moderate to severe intellectual disability may be difficult, as may be discerning a thought disorder (psychosis) in someone with autism and intellectual disability.

Although mental illness is generally of biologic origin and responds to medication, behavioral disorders can result from a mismatch between the child's abilities and the demands of the situation, organic problems, and/or family difficulties. They may represent attempts by the child to communicate, gain attention, or avoid frustration. In assessing the challenging behavior, one must also consider whether it is inappropriate for the child's *mental age,* rather than the *chronological age.* When intervention is needed, an environmental change, such as a more appropriate classroom setting, may improve certain behavior problems. Behavior management techniques are useful; psychopharmacologic agents may be appropriate in certain situations.

Medication is not useful in treating the core symptoms of intellectual disability; no agent has been found to improve intellectual function. Medication may be helpful in treating associated behavioral and psychiatric disorders. Psychopharmacology is generally directed at specific symptom complexes including ADHD (stimulant medication), self-injurious behavior and aggression (neuroleptics), and anxiety obsessive-compulsive disorder, and depression (selective serotonin reuptake inhibitors). Before long-term therapy with any psychopharmacologic agent is initiated, a short trial should be conducted. Even if a medication proves successful, its use should be reevaluated at least yearly to assess the need for continued treatment.

SUPPORTIVE CARE AND MANAGEMENT

Each child with intellectual disability needs a medical home with a pediatrician who is readily accessible to the family to answer questions, help coordinate care, and discuss concerns. Pediatricians can have effects on patients and their families that are still felt decades later. The role of the pediatrician includes involvement in prevention efforts, early diagnosis, identification of associated deficits, referral for appropriate diagnostic and therapeutic services, interdisciplinary management, provision of primary care, and advocacy for the child and family. The management strategies for children with an intellectual disability should be multimodal, with efforts directed at all aspects of the child's life: health, education, social and recreational activities, behavior problems, and associated impairments. Support for parents and siblings should also be provided.

Primary Care

For children with an intellectual disability, primary care has a number of important components:

- Provision of the same primary care received by all other children of similar chronological age (see Chapter 5)
- Anticipatory guidance relevant to the child's level of function: feeding, toileting, school, accident prevention, sexuality education
- Assessment of issues that are relevant to that child's disorder: e.g., examination of the teeth in children who exhibit bruxism, thyroid function in children with Down syndrome, cardiac function in Williams syndrome (see Chapter 108)

The American Academy of Pediatrics has published a series of guidelines for children with specific genetic disorders associated with intellectual disability (Down syndrome, fragile X syndrome, and Williams syndrome). Goals should be considered and programs adjusted as needed during the primary care visit. Decisions should also be made about what additional information is required for future planning or to explain why the child is not meeting expectations. Other evaluations, such as formal psychologic or educational testing, may need to be scheduled.

Interdisciplinary Management

The pediatrician has the responsibility for consulting with other disciplines to make the diagnosis of intellectual disability and coordinate treatment services. Consultant services may include psychology, speech-language pathology, physical therapy, occupational therapy, audiology, nutrition, nursing, and/or social work, as well as medical specialties such as neurodevelopmental disabilities, neurology, genetics, psychiatry, developmental-behavioral pediatricians, and/or surgical specialties. Contact with early intervention and school personnel is equally important to help prepare the child's Individual Family Service Plan/Individual Educational Plan. The family should be an integral part of the planning and direction of this process. Care should be family centered and culturally sensitive; for older children, their participation in planning and decision making should be promoted to whatever extent possible.

Periodic Reevaluation

The child's abilities and the family's needs change over time. As the child grows, more information must be provided to the child and family, goals must be reassessed, and programming needs should be adjusted. A periodic review should include information about the child's health status as well as the child's functioning at home, at school, and in other community settings. Other information, such as formal psychologic or educational testing, may be helpful. Reevaluation should be undertaken at routine intervals (6-12 mo during early childhood), at any time the child is not meeting expectations, or when the child is moving from one service delivery system to another. This is especially true during the transition to adulthood, beginning at age 14 yr as mandated by the IDEA Amendments of 2004. This transitioning should include the transfer of care to the adult healthcare system by age 21 yr.

Educational Services

Education is the single most important discipline involved in the treatment of children with an intellectual disability. The educational program must be relevant to the child's needs and address the child's individual strengths and weaknesses. The child's developmental level, the child's requirements for support, and goals for independence provide a basis for establishing an Individualized Education Program for school-age children, as mandated by federal legislation.

Leisure and Recreational Activities

The child's social and recreational needs should be addressed. Although young children with intellectual disability are generally included in play activities with children who have typical development, adolescents with intellectual disability often do not have opportunities for appropriate social interactions. Participation in sports should be encouraged, even if the child is not competitive, because it offers many benefits,

Table 36-4 Severity of Intellectual Disability and Adult Age Functioning

LEVEL	MENTAL AGE AS ADULT*	ADULT ADAPTATION
Mild	9-11 yr	Reads at 4th-5th grade level; simple multiplication and division; writes simple letter, lists; completes job application; basic independent job skills (arrive on time, stay at task, interact with coworkers); uses public transportation, might qualify for driver's license; keeps house, cooks using recipes
Moderate	6-8 yr	Sight-word reading; copies information, e.g., address from card to job application; matches written number to number of items; recognizes time on clock; communicates; some independence in self-care; housekeeping with supervision or cue cards; meal preparation, can follow picture recipe cards; job skills learned with much repetition; uses public transportation with some supervision
Severe	3-5 yr	Needs continuous support and supervision; might communicate wants and needs, sometimes with augmentative communication techniques
Profound	<3 yr	Limitations of self-care, continence, communication, and mobility; might need complete custodial or nursing care

*WHO, *International Statistical Classification of Diseases and Related Health Problems,* 10th revision, Geneva, Switzerland, 2011, World Health Organization.

including weight management, development of physical coordination, maintenance of cardiovascular fitness, and improvement of self-image. Social activities are equally important, including dances, trips, dating, and other typical social and recreational events.

Family Counseling

Many families adapt well to having a child with intellectual disability, but some have emotional or social difficulties. The risks of parents' depression and child abuse and neglect are higher in this group of children than in the general population. Among the factors that have been associated with good family coping and parenting skills are stability of the marriage, good parental self-esteem, limited number of siblings, higher socioeconomic status, lower degree of disability or associated impairments, parents' appropriate expectations and acceptance of the diagnosis, supportive extended family members, and availability of community programs and respite care services. In families in which the emotional burden of having a child with intellectual disability is great, family counseling, parent support groups, respite care, and home health services should be an integral part of the treatment plan.

PROGNOSIS

In children with severe intellectual disability, the prognosis is often evident by early childhood. Mild intellectual disability might not always be a lifelong disorder. Children might meet criteria for intellectual disability at an early age, but later the disability can evolve into a more specific developmental disorder (communication disorder, autism, slow learner, or borderline normal intelligence). Others with a diagnosis of mild intellectual disability during their school years develop sufficient adaptive behavior skills so that they no longer fit the diagnosis as adolescents, or the effects of maturation and plasticity can result in children moving from one diagnostic category to another (from moderate to mild retardation). Some children who have a diagnosis of a specific learning disability or communication disorder might not maintain their rate of cognitive growth and fall into the range of intellectual disability over time. By adolescence, the diagnosis has generally stabilized.

The apparent higher prevalence of intellectual disability in low and middle income group countries is of concern given the limitations in available resources. While community-based rehabilitation is being implemented in more than 90 countries, the efficacy of such programs has not been established.

The long-term outcome of persons with intellectual disability depends on the underlying cause, the degree of cognitive and adaptive deficits, the presence of associated medical and developmental impairments, the capabilities of the families, and the school and community supports, services, and training provided to the child and family (Table 36-4). As adults, many persons with mild intellectual disability are capable of gaining economic and social independence with functional literacy. They might need periodic supervision, especially when under social or economic stress. Most live successfully in the community, either independently or in supervised settings. Life expectancy is not adversely affected by intellectual disability itself.

For persons with moderate intellectual disability, the goals of education are to enhance adaptive abilities and "survival" academic and vocational skills so they are better able to live in the adult world (see Table 36-4). The concept of supported employment has been very beneficial to these individuals; the person is trained by a coach to do a specific job in the setting in which the person is to work. This bypasses the need for a sheltered workshop experience and has resulted in successful work adaptation in the community for many people with an intellectual disability. These persons generally live at home or in a supervised setting in the community.

As adults, people with severe to profound intellectual disability usually require extensive to pervasive supports (see Table 36-4). These individuals may have associated impairments, such as cerebral palsy, behavioral disorders, epilepsy, or sensory impairments, that further limit their adaptive functioning. They can perform simple tasks in supervised settings. Most people with this level of intellectual disability are able to live in the community with appropriate supports.

Children with Special Needs

PART V

Chapter 37

Adoption

Samantha L. Wilson and Mark D. Simms

Adoption is a social, emotional, and legal process that provides a new family for a child when the birth family is unable or unwilling to parent. In the United States, about 1 million children <18 yr of age are adopted; 2-4% of all American families have adopted. Annually across the globe, approximately 250,000 children are adopted; approximately 30,000 of adoptions are between nations. In the United States approximately **136,000 children were adopted in 2008, a** 15% increase since 1990. Of these, approximately 40% were stepparent or relative adoptions. Of non-stepparent adoptions, approximately 60% were from the child welfare system, 25% were international, and 15% were voluntarily adoption-placed domestic infants. Public agencies support approximately 50% of total annual adoptions in the United States, private agencies facilitate approximately 25% of adoptions, and independent practitioners, for example, lawyers, handle approximately 15% of adoptions. Compared to 19% of the general population, approximately 39% of adopted children have special healthcare needs.

The Adoption and Safe Families Act (P.L. 105-89) requires children in foster care to be placed with adoptive families if they cannot be safely returned to their families within a reasonable period of time. In fiscal year (FY) 2011, there were 104,236 children waiting for adoption, including 61,361 whose biological parents' rights had been terminated. Many children awaiting adoption have "special needs" because they are of school age, part of a sibling group, members of historically oppressed racial/ethnic groups, or because they have considerable physical, emotional, or developmental needs. A number of policy efforts are aimed at increasing adoption opportunities for these children, including federal adoption subsidies, tax credits, recruitment efforts to identify ethnically diverse adults willing to adopt, increased preplacement services, and expanding adoption opportunities to single adults, gay/lesbian partners, and older couples.

Along with foster care adoptions, international adoptions are a way of providing stable, long-term care to vulnerable children throughout the world. There is concern that in some countries of origin the rapid growth of international adoption has outpaced regulation and oversight to protect vulnerable children/families. Opportunities for financial gain have led to abuses, including the sale and abduction of children, bribery, and financial coercion of families, though the extent and scope of the potential concern is difficult to ascertain. Increasing global efforts, such as the Hague Convention on Protection of Children and Co-Operation In Respect of Intercountry Adoption, have promoted political cooperation between nations and established international law to reduce potential for child abduction/trafficking and to ensure that the best interests of the child are paramount in decision making. Participating nations, including the United States, are working to address the myriad sociopolitical conditions that create the need for out-of-family care, and are working to support children within their nations' borders. International adoption is increasingly considered a measure of last resort if the child cannot be cared for within the child's birth family (including extended relatives), the immediate community, or within the larger national culture. As a result, children adopted internationally into the United States are more likely to enter their families at older ages or with complex medical/developmental/social-emotional needs.

Although the vast majority of children adopted internationally *enter* the United States for purposes of adoption, there are a small, but growing, number of children who *exit* the United States for adoption into other countries. For example, in FY 2012, 99 children exited the United States for adoption by families in other countries (e.g., Canada, Netherlands, Ireland, United Kingdom). Little is known about the circumstances surrounding these adoptions and the eventual outcomes of the children who are adopted internationally *from* the United States.

In 2012, U.S. families adopted 8,868 children from other countries (compared with a peak of 22,884 in 2004). Children from China, Ethiopia, Russia, and South Korea represented 65% of children adopted internationally into the United States in 2012; 33% were from China alone. Although individual experiences vary, most children placed for international adoption have some history of poverty and social hardship in their home countries, and approximately 65% are adopted from orphanage/institutional settings. Many young infants are placed into orphanage care shortly after birth, while some older children have experienced family disruption resulting from parental illness, war, or natural disasters. Still others enter orphanage care following determination of significant abuse/neglect within their biologic families. The effects of institutionalization and other life stresses impact all areas of early growth and development. As a result, many children require specialized support and understanding to overcome the impact of stress and early adversity and to reach their full potential.

ROLE OF PEDIATRICIANS

Preadoption Medical Record Reviews

Adoption agencies are making increased efforts to obtain biological family health information and genetic histories to share with adoptive families prior to adoption. Pediatricians can help prospective adoptive parents understand the health and developmental history of a child and available background information from birth families in order to assess actual and potential medical risk factors to support adult decision making about the family's ability to parent the waiting child. Under the Hague Convention on Protection of Children and Co-operation in Respect of Intercountry Adoption, agencies in the United States that arrange international adoptions must make efforts to obtain accurate and complete health histories on children awaiting adoption.

The nature and quality of medical and genetic information, when available, varies greatly. Poor translation and use of medical terminology and medications that are unfamiliar to U.S.-trained physicians are quite common. Results of specific diagnostic studies and laboratory tests performed outside of the United States should not be relied on and **should be repeated** once the child arrives in the United States. Paradoxically, review of the child's medical records may raise more questions than provide answers. Each medical diagnosis should be considered carefully before being rejected or accepted. Country-specific growth curves should be avoided as they may be inaccurate or reflect a general level of poor health and nutrition in the country of origin. Instead, serial growth data should be plotted on U.S. standard growth curves; they may reveal a pattern of poor growth as a consequence of malnutrition or other chronic illness. Photographs or videotapes/DVDs may provide the only "objective" information from which medical status can be determined. Full-face photographs may reveal dysmorphic features consistent with fetal alcohol syndrome (see Chapter 106.2) or findings suggestive of other congenital disorders.

Preadoptive medical record reviews are also of potential value within the context of U.S. domestic adoptions. Biological family health information and genetic histories are often shared with adoptive families prior to adoption, and such information may become increasingly

relevant to the child as the child ages. The increase in "open" domestic adoptions, which encourages some degree of communication between participating biological and adoptive family members, may provide opportunities for long-term communication about medical and genetic conditions that might affect the adopted child.

In both international and domestic adoptions, frank interpretations of available information should be shared with the prospective adoptive parents. As noted by the American Academy of Pediatrics Committee on Early Childhood, Adoption and Dependent Care (1991), "It is not the pediatrician's role to judge the advisability of a proposed adoption, but it is appropriate and necessary that the prospective parents and any involved agency be apprised clearly and honestly of any special health needs detected now or anticipated in the future."

Postadoption Medical Care

Arrival Visit–International Adoption

All children with symptoms of an acute illness should receive immediate medical care after arriving in the United States. However, a significant number of children adopted internationally have acute or chronic medical problems that are not always immediately evident, including growth deficiencies, anemia, elevated blood lead, dental decay, strabismus, birth defects, developmental delay, feeding and sensory difficulty, and social-emotional concerns (see Chapter 37.1 below). After the child is settled in the new home, pediatricians should encourage adoptive parents to seek a comprehensive assessment of the child's growth and development. The American Academy of Pediatrics recommends that all children who are adopted from other countries undergo routine screening for infectious diseases and disorders of growth, development, vision, and hearing (Tables 37-1 and 37-2). Additional tests (e.g., malaria) should be ordered depending on the prevalence of disease in the child's country of origin (see Centers for Disease Control and Prevention's interactive malaria map at http://www.cdc.gov/malaria/map/). If the child's purified protein derivative is negative, a repeat skin test should be performed in 4-6 mo; children may have false-negative tests because of poor nutrition. A positive purified protein derivative should be followed by a QuantiFERON-TB Gold test to determine if the response is the result of prior bacillus Calmette-Guérin vaccination (see Chapter 215). If they have not received hepatitis A vaccine prior to arriving in the United States, parents, other caregivers, and family members (siblings, grandparents, etc.) should also be immunized. In 1 survey, 65% of internationally adopted children had no written records of overseas immunizations; however, those with records appeared to have valid records, although doses were not necessarily acceptable according to the U.S. schedule (see Chapter 172). The diverse medical and developmental needs of internationally adopted children have led to the creation of specialty clinics throughout the United States, which may be a valuable resource for adoptive families at all stages in the adoption process.

Table 37-1 Recommended Screening Tests for International Adoptees Upon U.S. Arrival

Screening tests
- Complete blood cell count
- Hemoglobin identification
- Blood lead level
- Urinalysis
- Newborn screening (children <12 mo)
- Vision and hearing screening
- Developmental testing

Other screening tests to consider based on clinical findings and age of the child
- Detection of *Helicobacter pylori* antibody or ^{13}C-urea breath test
- Stool cultures for bacterial pathogens
- Glucose-6-phosphate dehydrogenase deficiency screening
- Sickle cell
- Urine pregnancy test

Infectious disease screening (see Table 37-2)

Developmental Delays

At the time of adoption, many children exhibit delays in at least 1 area of development, but most exhibit significant gains within the first 12 mo after adoption. Those adopted before 6 mo of age usually demonstrate typical development, whereas those adopted at older ages have more variable outcomes. In the immediate postadoption period, it may be impossible to determine with any certainty whether a child's developmental delays will be transient or long-lasting. Careful monitoring of development within the first year of adoption can identify a "developmental trend" over time that may be more predictive of long-term functioning than assessment at any specific point in time.

Growth Delays

Physical growth delays are common in both domestically and internationally adopted children, and may represent the combined result of many factors, for example, unknown/untreated medical conditions, malnutrition, and psychological deprivation. Weight and height at the time of adoption have been negatively correlated with the amount of time the child spent in adverse environments (i.e., orphanage care or in the care of highly neglectful biological families). Though most children experience a significant catch-up in physical growth following adoption, many remain shorter than their U.S. peers.

Language Development

For both domestic and international adoptees, genetic or biologic risk factors for poor language development may not have been identified preadoptively. Children adopted internationally typically have had little exposure to English, and it may not be possible to assess a child's language abilities until they have had a chance to learn English. Most internationally adopted children of pre–school-age are able to attain English language skills equal to those born in the United States within 24 mo postadoption. In older children, delays in native language skills often predict delays in English acquisition. If language concerns persist following 1-2 yr in an enriching environment, assessment by a speech-language pathologist may be warranted.

Table 37-2 Screening Tests for Infectious Diseases in International Adoptees

RECOMMENDED TESTS

Hepatitis B virus serologic testing*
- Hepatitis B surface antigen (HBsAg)
- Antibody to hepatitis B surface antigen (anti-HBs)

Hepatitis C virus serologic testing*†
Hepatitis A virus serologic testing†
Varicella virus serologic testing†
Syphilis serologic testing
- Nontreponemal test (RPR, VDRL, or ART)
- Treponemal test (MHA-TP or FTA-ABS)

Human immunodeficiency viruses 1 and 2 testing (ELISA if >18 mo, PCR if <18 mo)*
Complete blood cell count with red blood cell indices and differential (if eosinophilia, see text)
Stool examination for ova and parasites (2-3 specimens)†
Stool examination for *Giardia lamblia* and *Cryptosporidium* antigen (1 specimen)†
Tuberculin skin test (with CXR if >5 mm induration) or interferon-γ release assay*†

OPTIONAL TESTS (FOR SPECIAL POPULATIONS OR CIRCUMSTANCES)

GC/Chlamydia
Chagas disease serology
Malaria thick and thin smears

Eating Concerns

Initial concerns about eating, sleep regulation, and repetitive (e.g., self-stimulating or self-soothing) behaviors are common, especially among children adopted following a high degree of neglect or developmental trauma. Feeding concerns are sometimes linked to limited exposure to textured or solid foods during later infancy/toddlerhood. Children who have experienced chronic lack of food may not have developed an awareness of satiation cues, leading to hoarding or frequent vomiting. Feeding concerns often subside gradually with introduction of age-appropriate foods and parental support for positive feeding practices. Many children who were adopted following a significant period of malnutrition may eat an excessive amount of food. Unless the child is eating to the point of vomiting (which would indicate little awareness of satiation cues), it is generally best to allow them to eat until satiation. Typically within 6 mo, the child will regulate food intake appropriately. Occasionally, additional support from a speech pathologist or feeding specialist is warranted to address possible physical/psychological concerns that could impede proper feeding.

Sleep Concerns

Sleep is often disrupted as the child reacts to changes in routines and environments. Efforts to create continuity between the preadoption and postadoption environment can be helpful. Within the first 3-6 mo, as the child's emotional self-regulation improves, many sleep concerns subside. Similarly, stereotypic behaviors, such as rocking or head banging, often diminish within the first few months following adoption.

Social and Emotional Development

Dyadic interactions between child and caretaker are a critical component to later regulatory functioning and social-emotional development. The amount and quality of individualized caretaking children have received prior to their adoption is usually unknown. In many instances, entry into a secure, stable home setting with consistent child-caring routines is sufficient to support the child's emerging social-emotional development. At times, the child's prior experiences or biologic disposition may result in behavior that is confusing to the adoptive parents. The child's reactions may be subtle or difficult to interpret, interfering with the parents' ability to respond in a sensitive manner. In these circumstances, additional support may be helpful to foster the emerging relationships and behavioral regulation in the newly formed family.

Racial Identity Development

An estimated 22% of adoptive families are interracial (where the racial background of the child differs from that of the parent/parents). In the vast majority of these adoptive placements, children of color have been adopted by white parents. Racial identity development, including ways to understand and respond to discrimination, is increasingly recognized as important in the overall development of children. Surveys of adults adopted transracially indicate that racial identity is of central importance at many ages, and tends to increase in significance during young adulthood. Integrating race/ethnicity into identity can be a complex process for all children, but it may be especially complicated when they are raised in a family where racial differences are noted. Adults raised within interracial families have noted the value of attending racially diverse schools and of having adult role models (e.g., teachers, doctors, coaches) who share their racial background. Parents who adopt transracially are often encouraged to support interactions within diverse communities and to discuss race (and associated discrimination) often within the family.

Toxic Stress

The cumulative amount of early adversity (e.g., numerous years within international orphanage care, extensive abuse/neglect prior to removal from biological family, or multiple foster care placements) experienced by a child prior to adoption, referred to as "toxic stress," can impact both immediate placement stability and long-term functioning. The degree of presumed toxic stress may be helpful in interpreting a child's behavior and supporting family functioning (see video at http://developingchild.harvard.edu/resources/multimedia/videos/three_core_concepts/toxic_stress/).

Family Support

There are unique aspects to adoptive family formation that can create familial stress and impact child and family functioning. Some adoptive families may have to address infertility, creation of a multiracial family, disclosure of adoptive status, concerns and questions the child may have about their biologic origins, and ongoing scrutiny by adoption agencies. In the case of gay/lesbian parents, there are often additional psychosocial stressors, including continued barriers to legal recognition of both parents in a gay/lesbian partnership that can negatively impact family functioning. Although most families acclimate well to adoption-related stressors, some parents experience post adoption depression and may benefit from additional support to ease the family's transition.

Adoption Narrative

Families are encouraged to speak openly and repeatedly about adoption with their child, beginning in the toddler years and continuing through adolescence. Creating a "Lifebook" for the adopted child provides a way to support family communication about the child's history and significant relationships (including birth family members) and to document the child's important life transitions (e.g., through foster care or immigration to the United States). It is common, and normal, for children to have questions about adoption and their biological family throughout their development. An increase in cognitive understanding between ages 7 and 10 yr can sometimes increase adoption-related questions and/or distress. Youth who have questions about biological family members are increasingly able to access information via web-based searching, raising the importance of ongoing open communication about adoption. Pediatricians may need to respond to increased concerns/questions when the adoptee's health and genetic history is incomplete or unknown. At any time, concerns about development, behavior, and social-emotional functioning may or may not be related to the child's adoption history.

The vast majority of adopted children and families adjust well and lead healthy, productive lives. It is not common for adoptions to disrupt; disruption rates are higher among children adopted from foster care, which research associates with their age at time of adoption and/or a history of multiple placements prior to adoption. As a result of a greater understanding of the needs of families who adopt children from foster care, agencies are placing greater emphasis on the preparation of adoptive parents and ensuring the availability of a full range of postadoption services, including physical health, mental health, and developmental services for their adopted children.

37.1 Medical Evaluation of Immigrant (Foreign-Born) Children for Infectious Diseases

Stacene R. Maroushek

More than 210,000 foreign-born children (≤16 yr old) enter the United States each year as asylees, refugees, and immigrants including international adoptees. This number does not include undocumented children living and working in the United States, the U.S.-born children of foreign-born parents, or the approximately 2.7 million nonimmigrant visitors ≤16 yr old who legally enter the United States annually with temporary visas. With the exception of internationally adopted children, pediatric guidelines for screening these newly arrived children are sparse. The diverse countries of origin and patterns of infectious disease, the possibility of previous high-risk living circumstances (e.g., refugee camps, orphanages, foster care, rural/urban poor), the

limited availability of reliable healthcare in many economically developing countries, the generally unknown past medical histories, and interactions with parents who may have limited English proficiency, varied educational, or economic experiences, make the medical evaluation of immigrant children a challenging but important task.

Before admission into the United States, all immigrant children are required to have a medical examination performed by a physician designated by the U.S. Department of State in their country of origin. This examination is limited to completing legal requirements for screening for certain communicable diseases and examination for serious physical or mental defects that would prevent issuing a permanent residency visa. This evaluation is not a comprehensive assessment of the child's health and, except in limited circumstances, laboratory or radiographic screening for infectious diseases **is not required** for children <15 yr old. After entry into the United States, health screenings of refugees, but not other immigrants, are recommended to be done by the resettlement state. There is little tracking of refugees as they move to different cities or states. Thus, many foreign-born children have had minimal prearrival or postarrival screening for infectious diseases or other health issues.

Immunization requirements and records also vary depending on entry status. Internationally adopted children who are younger than 10 yr are exempt from Immigration and Nationality Act regulations pertaining to immunization of immigrants before arrival in the United States. Adoptive parents are required to sign a waiver indicating their intention to comply with U.S.-recommended immunizations, whereas older immigrants need only show evidence of up-to-date, not necessarily complete, immunizations before application for permanent resident (green card) status after arrival in the United States.

Infectious diseases are among the most common medical diagnoses identified in immigrant children after arrival in the United States. Children may be asymptomatic; therefore, diagnoses must be made by screening tests in addition to history and physical examination. Because of inconsistent perinatal screening for hepatitis B and hepatitis C viruses, syphilis, and HIV, and the high prevalence of certain intestinal parasites and tuberculosis, all foreign-born children should be screened for these infections on arrival in the United States. Table 37-2 lists suggested screening tests for infectious diseases. In addition to these infections, other medical and developmental issues, including hearing, vision, dental, and mental health assessments; evaluation of growth and development; nutritional assessment; lead exposure risk; complete blood cell count with red blood cell indices; microscopic urinalysis; newborn screening (this could be done in nonneonates, too) and/or measurement of thyroid-stimulating hormone concentration; and examination for congenital anomalies (including fetal alcohol syndrome) should be considered as part of the initial evaluation of any immigrant child.

Children should be examined within 1 mo of arrival in the United States or earlier if there are immediate health concerns, but foreign-born parents may not access the healthcare system with their children unless prompted by illness, school vaccination, or other legal requirements. I**t is important to assess the completeness of previous medical screenings at any first visit with a foreign-born child**.

Clinicians should be aware of potential diseases in high-risk immigrant children and their clinical manifestations. Some diseases, such as central nervous system cysticercosis, may have incubation periods as long as several years, and thus may not be detected during initial screening. On the basis of findings at the initial evaluation, consideration should be given to a repeat evaluation 6 mo after arrival. In most cases, the longer the interval from arrival to development of a clinical syndrome, the less likely the syndrome can be attributed to a pathogen acquired in the country of origin.

COMMONLY ENCOUNTERED INFECTIONS

Hepatitis B

See Chapter 350.

The prevalence of hepatitis B surface antigen (HBsAg) in international adoptees and refugee children ranges from 1-5% and 4-14%, respectively, depending on the country of origin, age, and year studied. Prevalence of markers of past hepatitis B virus (HBV) infection is higher. HBV infection is most prevalent in immigrants from Asia, Africa, and some countries in Central and Eastern Europe, as well as the former Soviet Union (e.g., Bulgaria, Romania, Russia, and Ukraine), but also occurs in immigrants born in other countries. All immigrant children, even if previously vaccinated, coming from high-risk countries (HBsAg seropositivity >2%) should undergo serologic testing for HBV infection, including both HBsAg and antibody to HBsAg (anti-HBs), to identify current or chronic infection, past resolved infection, or evidence of previous immunization. Because HBV has a long incubation period (6 wk to 6 mo), the child may have become infected at or near the time of migration and initial testing might be falsely negative. Therefore, strong consideration should be given to a repeated evaluation 6 mo after arrival for all children, especially those from highly endemic countries. Chronic HBV infection is indicated by persistence of HBsAg for more than 6 mo. Children with HBsAg-positive test results should be evaluated to identify the presence of chronic HBV infection because chronic hepatitis B infection occurs in >90% of infants infected at birth or in the first year of life, and in 30% of children exposed at ages 1-5 yr. Once identified as being infected, additional testing to assess for biochemical evidence of severe or chronic liver disease or liver cancer should take place.

Hepatitis A

See Chapter 358.

Hepatitis C

See also Chapter 358.

The decision to screen children should depend on history (e.g., receipt of blood products; traditional percutaneous procedures such as tattooing, body piercing, circumcisions, or other exposures to reused, unsterile medical devices) and the prevalence of infection in the child's country of origin. Children from Eastern Mediterranean and Western Pacific countries, Africa, China, and Southeast Asia should be considered for hepatitis C infection screening. All children coming from Egypt, which has the highest known seroprevalence (12% nationally and 40% in some villages), should be tested for hepatitis C.

Intestinal Pathogens

Fecal examinations for ova and parasites by an experienced laboratory will identify a pathogen in 15-35% of internationally adopted children; prevalence rates in immigrants and refugees range from 8-86%. The prevalence of intestinal parasites varies by country of origin, time period when studied, previous living conditions (including water quality, sanitation, and access to footwear) and the age of the child, with toddler/young school-age children being most affected. If documented predeparture treatment was given, an eosinophil count should be performed. An absolute eosinophil count of >400 cells/µL, if persistently elevated for 3-6 mo after arrival, should prompt further investigation for tissue-invasive parasites such as *Strongyloides* (see Chapter 295) and *Schistosoma* (see Chapter 300) species. If no documented predeparture treatment was given, 2 stool ova and parasite specimens obtained from separate morning stools should be examined by the concentration method, and an eosinophil count should be performed. If the child is symptomatic, including evidence of poor physical growth, but no eosinophilia is present, a single stool specimen should also be sent for *Giardia lamblia* (see Chapter 282) and *Cryptosporidium parvum* (see Chapter 283) antigen detection. All potentially pathogenic parasites found should be treated appropriately. All nonpregnant refugees >2 yr of age coming from sub-Saharan Africa and Southeast Asia should be presumptively treated with predeparture albendazole.

Tuberculosis

See also Chapter 215.

Tuberculosis (TB) commonly is encountered in immigrants from all countries because *Mycobacterium tuberculosis* infects approximately 30% of the world's population. Latent TB infection rates range from 0.6-30% in adoptees and up to 60% in some refugee children from North Africa and the Middle East. Prior to 2007, chest radiographs or

tuberculin skin tests were generally not administered in children <15 yr of age and reports indicate that 1-2% of these unscreened children may enter the United States with undiagnosed active TB disease.

Since 2007, TB Technical Instructions for Medical Evaluation of Aliens have required that children ages 2-14 yr undergo a TB skin test if they are medically screened in countries where the TB rate is 20 cases or more per 100,000 population. If the skin test is positive, a chest x-ray is required. If the chest x-ray suggests TB, cultures and 3 sputum smears are required, all before arrival in the United States. This requirement is being phased in over a number of years, and some countries with a case rate of 20 per 100,000 may not currently be screening children. Check with the Centers for Disease Control and Prevention, Division of Global Migration and Quarantine for latest information (www.cdc.gov/ncidod/dq/technica.htm).

Congenital Syphilis

See Chapter 218.

HIV Infection

See Chapter 276.

Immunizations

See Chapter 172.

Immigrant children and adolescents should receive immunizations according to the recommended schedules in the United States for healthy children and adolescents. Some immigrants will have written documentation of immunizations received in their birth or home country. Although immunizations such as bacillus Calmette-Guérin, diphtheria and tetanus toxoids, and pertussis (DTP), poliovirus, measles, and hepatitis B virus vaccines often are documented, other immunizations, such as *Haemophilus influenzae* type b, mumps, and rubella vaccines, are given less frequently, and *Streptococcus pneumoniae*, human papillomavirus, meningococcal, and varicella vaccines are given rarely. When doubt exists, an equally acceptable alternative is to reimmunize the child. Because the rate of more serious local reactions after diphtheria, tetanus toxoid, and acellular pertussis vaccine increases with the number of doses administered, serologic testing for antibody to tetanus and diphtheria toxins before reimmunizing, or if a serious reaction occurs, can decrease risk.

In children older than 6 mo with or without written documentation of immunization, testing for antibodies to diphtheria and tetanus toxoid and poliovirus may be considered to determine whether the child has protective antibody concentrations. If the child has protective concentrations, then the immunization series should be completed as appropriate for that child's age. In children older than 12 mo, measles, mumps, rubella, and varicella antibody concentrations may be measured to determine whether the child is immune; these antibody tests should not be performed in children younger than 12 mo because of the potential presence of maternal antibody.

Chapter 38

Foster and Kinship Care

Moira Szilagyi

The placement of children in out-of-home care has served the needs of children in many societies worldwide throughout history. The institution of foster care was developed in the United States as a temporary resource for children during times of family crisis and is rooted in the principle that children fare best when raised in family settings. The 1989 United Nations Convention on the Rights of the Child, a legally binding international instrument, addresses the need for such care for all children worldwide. Regardless of its setting, the mission of foster care is to provide for the safety, permanency, and well-being of children while assisting their families with services to promote reunification.

EPIDEMIOLOGY

The number of children in foster care worldwide is unknown, although it has been estimated that 8 million may be in foster and residential care. On September 11, 2011, approximately 400,540 children in the United States resided in foster care, representing a downward trend since 1999, when the daily average of children in care was 567,000. This decrease has occurred despite an increase in maltreatment reports, as child welfare offers families more preventive services and placement with relatives or nonrelative caregivers (kinship care) as an alternative to removal, resulting in fewer admissions. Reunification rates and adoption of children from foster care have also increased. Court ordered and informal kinship care have increased, accounting for up to 7% of children.

Approximately 33% of children in foster care in the United States are younger than the age of 5 yr and 35% are older than age 12 yr. The largest subset is white (41%) with significant percentages of black (27%) and Hispanic (21%) children. The average length of stay has dropped to a mean of 23.9 mo (median: 13.5 mo), although 31% of children remain in foster care for more than 2 yr. Only approximately 52% of children achieve reunification. Approximately 8% go to relatives, while approximately 20% (50,000 children) are adopted out of foster care annually. Among remaining children, 11% emancipate, 6% enter into long-term state guardianship, 1% run away, and 2% transfer to other institutions. In 2011, there were 343 deaths in foster care.

Most children live in nonrelative foster (47%) or certified relative foster (27%) family care, and 4% reside in a preadoptive home, although this is less than 20% of the children who are awaiting adoption. Approximately 15%, mostly adolescents, live in group homes or residential settings. The average number of placements a child experiences in foster care is not included in Adoption and Foster Care Reporting System, but important predictors include severe behavioral and/or developmental problems, larger sibling group size, and longer time spent in foster care. Within 12 months, nearly all emancipated youth have at least one homeless night and, within a decade, less than half have a high school degree and most are living in poverty and have high rates of posttraumatic stress disorder and depression.

LEGISLATION IN THE UNITED STATES

In the United States, the Adoption and Safe Families Act (P.L. 105-89), passed in 1997, requires that a permanency plan be made for each child no later than 12 months after entry into foster care and that a petition to terminate parental rights typically be filed when a child has been in foster care for at least 15 of the previous 22 months. The Fostering Connections and Promoting Adoptions Act of 2009 (P.L. 110-351) focused on incentives for guardianship and adoption, supports for the young adults at the age of emancipation, and rights of Native American children to care within their tribe. This latter act also contained a clause requiring states to develop and coordinate healthcare systems for children in foster care in collaboration with Medicaid and pediatricians.

EARLY CHILDHOOD TRAUMA LEADS TO POOR HEALTH OUTCOMES

Children in foster care have high rates of early childhood trauma and adversity. More than 70% have a history of abuse, neglect, or both. More than 80% have experienced significant domestic and/or community violence. Birth parents have high rates of mental illness, criminal justice system involvement, substance abuse, unemployment, and cognitive impairment. Many children have had prenatal substance exposure, multiple caregivers of varying quality, and are from families with long involvement with child protective services.

Removal from the family of origin may compound trauma although some children experience relief at removal from a chaotic, abusive, or dangerous home. Most children miss their family, worry about their parents and siblings, and long for reunification. Separation, loss and grief, unpredictable contact with birth parents, placement changes, the process of terminating parental rights, and the sheer uncertainty of foster care may further erode a child's well-being.

Childhood trauma is correlated with poor developmental, behavioral and health outcomes. Early trauma and chronic stress adversely affect the neurobiology of the developing brain, especially those areas involved in attention, emotional regulation, memory, executive function, and cognition. As a result, shortened attention span, hyperactivity, poorer cognitive function, aggression, and memory issues are problems encountered frequently encountered among children in foster care.

HEALTH ISSUES

Multiple childhood adversities and the receipt of fragmented and inadequate health services before placement into foster care mean that children enter foster care with a high prevalence of chronic medical, mental health, developmental, dental, and educational problems (Table 38-1), and so are defined as children with special healthcare needs. The greatest single healthcare need of this population is for high-quality, evidence-based mental health services to address the impacts of prior and ongoing trauma, loss, and unpredictability. In addition, they have higher rates of asthma, growth failure, obesity, vertically transmitted infections, and neurologic conditions than the general pediatric population. Adolescents need access to reproductive health and substance abuse services. Up to 60% of children <5 yr have a developmental delay in at least 1 domain and more than 40% of school-age children qualify for special education services. Unfortunately, educational difficulties persist despite improvements in school attendance and performance after placement in foster care.

Table 38-1 Health Issues of Children in Foster Care
CHRONIC MEDICAL PROBLEMS Affect 40-60% of children Asthma, dermatologic, neurologic, obesity, growth failure, hearing, and vision problems are most common
ABUSE AND NEGLECT >70% of children have a history of abuse and neglect at entry into foster care Monitor at all health visits for abuse or neglect
COMPLEX CHRONIC MEDICAL PROBLEMS Involves 10% of children in foster care Children may be dependent on medical technologies or have multiple disabilities
MENTAL HEALTH CONCERNS Affects 80% of children >4 yr of age Result of childhood trauma and adversity Most common diagnoses are adjustment disorder, posttraumatic stress disorder, attention-deficit/hyperactivity disorder, oppositional defiant disorder, and conduct disorder Externalizing problems are more likely to result in therapy
DEVELOPMENTAL PROBLEMS 60% of children <5 yr of age have at least 1 documented delay Commonly affect communication, cognition, problem-solving, and personal-social domains
DENTAL PROBLEMS 35% of children have significant dental disease
ADOLESCENT HEALTH ISSUES High rates of sexually transmitted infections, high-risk behaviors, and substance abuse
EDUCATIONAL PROBLEMS Half of special education placements relate to behavioral or emotional issues, not cognitive Only 32% of adolescents eventually graduate from high school; 32% obtain a General Equivalency Diploma
FAMILY RELATIONSHIP PROBLEMS 100% of children have family relationship problems

Although children in foster care are children with special healthcare needs, often they lack access to the services they need. Most public and private child welfare agencies do not have formal arrangements for accessing the needed array of health services and rely on local physicians and/or health clinics funded by Medicaid. Health histories are often sparse at admission because many have lacked regular care or their biological parents may not be available or forthcoming. Once children enter foster care, there is often a diffusion of responsibility across caregivers and child welfare. Foster parents usually receive little information about a child's healthcare needs, but they are typically expected to decide when and where children receive healthcare services. Child welfare case workers are responsible for ensuring that a child's health needs are addressed but coordination across multiple healthcare providers may be daunting. Uncertainty about who is legally responsible for making healthcare treatment decisions and who may have access to health information may delay or result in the denial of healthcare services.

HEALTHCARE FOR CHILDREN AND ADOLESCENTS IN FOSTER CARE

The American Academy of Pediatrics (AAP) and Child Welfare League of America published updated general guidelines for the healthcare of this special needs population in 2007. The AAP has published detailed healthcare standards for children in foster care, available on the *Healthy Foster Care America* website. Children should receive healthcare services in a medical home setting where they receive comprehensive healthcare that is continuous over time (Table 38-2). Compassionate, culturally competent healthcare that is trauma-informed means that health staff should understand the effects of past trauma and ongoing uncertainty and loss on a child's health and well-being, and that of their birth and foster families. Children should be seen early and often when they first enter foster care to identify all their health issues, and to support the child and foster parent through a major transition that involves considerable loss and adjustment for the child and many challenges for the foster parent.

The AAP recommends that every child in foster care have comprehensive medical, dental, developmental, and mental health assessments within 30 days of entering foster care. Almost every child in foster care deserves a full mental health evaluation to assess for the impact of trauma and loss on emotional well-being. Psychotropic medication should only be considered, if at all, after a thorough high-quality mental health evaluation by a pediatric-trained mental health professional. It is wise for the pediatrician to remember that inattention, impulsivity and hyperactivity may reflect the impact of past trauma on the developing brain rather than attention-deficit/hyperactivity disorder (see Chapter 33). Childhood trauma impairs cognition and memory (see Chapter 40) so that children <6 yr of age should receive a comprehensive developmental assessment, while older children should receive a comprehensive educational assessment. The caseworker should provide consents for healthcare and any available health history, and encourage the appropriate involvement of the birth parent. The primary care provider should help caseworkers and foster parents obtain and interpret the results of these assessments. Pediatricians, caregivers, and caseworkers should share health information.

Foster parents are the major therapeutic intervention of the foster care system, and pediatricians should provide them with appropriate education and support. Important topics include positive parenting strategies, supporting children through transitions, providing a consistent and nurturing environment, and helping children heal from past trauma and adversity (Table 38-3). Foster and birth parents may need extensive education about behavioral and emotional problems within the context of the child's trauma history to remove blame and promote healing. Minimizing conflict among caregivers is extremely important as a child ideally has affection and loyalty for all of the child's caregivers. Pediatricians should focus on both caregiver (foster and birth

Table 38-2 Pediatric Medical Home for Children in Foster Care

CHARACTERISTIC	APPLICATION IN FOSTER CARE
Comprehensive healthcare	Perform comprehensive admission assessment within 30 days of entry Ensure access to mental health, developmental, and dental evaluation and services Screen and refer as needed for abuse and neglect
Coordination of care	Make timely referrals and follow up subspecialist visits Communicate with caseworkers, foster parents, and legal professionals Maintain a comprehensive medical record despite changes in placement
Compassionate care	Understand and educate children, families, and other healthcare professionals on the impact of early childhood adversities, trauma and ongoing uncertainties of foster care on the developing child Promote positive purposeful parenting strategies and minimizing conflict among caregivers
Child-centered and family-focused care	Prioritize the needs of children first and foremost Partner with families to increase understanding of a child's needs Focus on the strengths of children and families
Continuity of care	Invite children to remain patients throughout their stay in foster care, and beyond when feasible
Cultural competence	Extend this concept to include the microculture of foster care and the multiple transitions that can further erode a child's well-being. Understand the roles of caseworkers, foster parents, law guardians, etc.
Accessibility	Create a welcoming environment for children and all of their families (birth, foster, kin, preadoptive)

Table 38-3 Anticipatory Guidance for Children in Foster Care

SITUATION	ANTICIPATORY GUIDANCE FOR FOSTER PARENTS
Preparing for visits	Educate foster/kinship parents about impact of visitation on children Send familiar object with child to visit Have child draw picture to give birth parent Reassure child that foster parent will be there when child returns from visits Advise all caregivers to minimize conflict with and negativity toward each other
Returning from visits and other transitions	Greet child warmly and help with unpacking Establish reentry rituals, such as quiet play, reading together, having a healthy snack
Relationship with birth parent(s)	Encourage caseworker to have birth parents keep child's rituals and routines consistent with those in foster home (vice versa when appropriate) Focus on birth parent's positive qualities; maintain a neutral affect
Building on child's strengths	Encourage participation in child-directed play. Encourage participation in normalizing activities (such as hobbies or sports) "Catch the child being good" Encourage specific praise Provide child with words for emotions Ignore negative behavior unless there is a safety issue
Preparing for court dates	Foster/kinship parent, caseworker or law guardian should explain purpose of court hearings to child in simple terms
School	If changing schools, visit school together a few times, and meet the teacher Check in regularly (weekly or monthly depending on need) with child's teacher
Adolescent	Decide what issues demand firm limits and guidelines (curfews, no smoking, party at a friend's house, etc.), what issues are not important and can be left up to teen (hair length and color, etc.) and what issues are ideal for negotiation (transportation to a school function, style of dress etc.) Encourage responsible decision-making by recognizing and complimenting it. Encourage after-school activities. Teach driving when age and developmentally appropriate Encourage teen to seek employment and teach job skills Help teen to identify mentors and focus on the future

parent) and child strengths. For teens and young adults in foster care, the pediatrician should provide anticipatory guidance around education, identity formation in the face of past trauma, independent decision making, health promotion, and developing the skills and competencies needed for a successful future life. The pediatrician should advocate for placement stability in a nurturing and responsive foster family where caregivers possess the appropriate skills to help children and youth heal.

Chapter 39

Impact of Violence on Children

Marilyn C. Augustyn and
Barry S. Zuckerman

The reach of violence, whether as the victim, perpetrator, or witness, whether in person or through the media, is far, deep, and long-standing across the globe (see Chapter 1). Exposure to violence disrupts the healthy development of children in a myriad of ways. Pediatric clinicians must be competent to address these issues in impacted children and families under their care and also have a wider responsibility to advocate on local, state, national, and international levels for safer environments in which all children can grow and thrive.

Witnessing violence is detrimental to children. Because their scars as bystanders are emotional and not physical, the pediatric clinician may not fully appreciate their distress and thereby miss an opportunity to provide needed interventions. For children not living in war zones, the source of first exposure to violence is often **intimate partner violence.** According to data from the National Center for Posttraumatic Stress Disorder (PTSD), 20-30% of American women will be physically abused by a partner at least once in their lifetimes. Similarly in the 2010 National Intimate Partner and Sexual Violence Survey administered by the Centers for Disease Control and Prevention (CDC), 1 in 4 women and 1 in 7 men have been the victim of severe physical violence by an intimate partner, affecting more than 12 million people each year. Slightly more than half of female victims of intimate partner violence live in households with children <12 yr of age; family violence is most likely to be perpetrated by those between the ages of 18 and 30 yr and most victims are impacting before 24 yr of age. Across studies, 7-23% of youths in general population surveys experienced exposure to intimate partner violence, 36-39% of youth in intimate partner violence cases have witnessed the violence, and 45-46% of primary caregivers in child maltreatment investigations have experienced intimate partner violence. In a national survey, 50% of the men who frequently assaulted their wives also frequently abused their children. Most of the children were injured when they intervened to protect their mother from her partner (see Chapter 40). Children who witness domestic violence are at higher risk for negative medical outcomes including increased risk of obesity, asthma, and PTSD. In addition, these children are at higher risk for other traumatic events; for example, in a sample of 120 preschool children (age 4-6 yr) exposed to intimate partner violence in the past 2 yr, 38% were exposed to additional traumatic events, including sexual assaults by family members, physical assaults, serious accidents, and/or life-threatening illnesses.

Another source of witnessed violence is **community violence.** Community violence in the United States is a serious problem that disproportionately affects children from low-income areas. According to the 2011 National Survey of Children's Exposure to Violence, approximately 22% of children had witnessed violence in their family or in their community in the year prior to the survey, and of all the horrors the survey inquired about—assaults and bullying, sexual victimization, maltreatment by a caregiver, and theft or vandalism—nearly 60% of children had experienced or witnessed one of them. Young children living in high crime and violence areas observe death more frequently and at younger ages than do children growing up in more secure surroundings. Witnessing acts of violence may be a significant stressor in children's lives. If children's coping skills are not sufficient to deal with violent situations, stress may be manifested as psychological, physical, or behavioral symptoms.

Table 39-1	Public Health Recommendations to Reduce Effects of Media Violence on Children and Adolescents

Parents should:
- Be made aware of the risks associated with children viewing violent imagery, as it promotes aggressive attitudes, antisocial behavior, fear, and desensitization
- Review the nature, extent, and context of violence in media available to their children before children view
- Assist children's understanding of violent imagery appropriate to their developmental level

Professionals should:
- Offer support and advice to parents who allow their children unsupervised access to extreme violent imagery as this could be seen as a form of emotional abuse and neglect
- Educate all young people in critical film appraisal, in terms of realism, justification, and consequences
- Exercise greater control over access to inappropriate violent media entertainment by young people in secure institutions
- Use violent film material in anger management programs under guidance

Media producers should:
- Reduce violent content and promote antiviolence themes and publicity campaigns
- Ensure that when violence is presented it is in context and associated with remorse, criticism, and penalty
- Ensure that violent action is not justified or its consequences understated

Policy makers should:
- Monitor the nature, extent, and context of violence in all forms of media and implement appropriate guidelines, standards, and penalties
- Ensure that education in media awareness is a priority and a part of school curricula

From Browne KD, Hamilton-Giachritsis C: The influence of violent media on children and adolescents: a public-health approach, Lancet *365:702-710, 2005.*

The most ubiquitous source of witnessing violence for children in the United States is **media violence.** The average child 2-5 yr of age watches 20-30 hr of television a week, hours that are increasingly filled with scenes of violence, not only on commercial television but also on news outlets. In addition, the wider array of "screen time" children are exposed to, including computer, smart phones, and video games, increases the opportunities for violent events to enter the lives of children. In particular, recent tragic events, including mass shootings and acts of terrorism, have increased the specter of fear among children. Although exposure to media violence cannot be equated to exposure to real-life violence, many studies confirm that media violence desensitizes children to the meaning and impact of violent behavior. Not all children are equally affected by media violence. Children most at risk from viewing violence may be children who are also exposed regularly to real-life violence in their homes and communities. Table 39-1 lists interventions to reduce exposure to media violence.

IMPACTS OF VIOLENCE

The violence children experience and witness also has a profound impact on health and development. In a cross-sectional analysis of a Head Start preschool-age cohort, being abused, exposure to domestic violence, and having a mother using substances were associated with a higher number of health problems. Beyond injuries, violence affects children psychologically and behaviorally; it may influence how they view the world and their place in it. Children can come to see the world as a dangerous and unpredictable place. This fear may thwart their exploration of the environment, which is essential to learning in childhood. Children may experience overwhelming terror, helplessness, and fear even if they are not immediately in danger. Preschoolers are most vulnerable to threats that involve the safety (or perceived safety) of their caretakers. High exposure to violence in older children correlates

with poorer performances in school, symptoms of anxiety and depression, and lower self-esteem. Violence, particularly domestic violence, can also teach children especially powerful early lessons about the role of violence in relationships. Violence may change the way that children view their future; they may believe that they could die at an early age and thus take more risks, such as drinking alcohol, abusing drugs, not wearing a seatbelt, and not taking prescribed medication.

Some children exposed to severe and/or chronic violence may suffer from PTSD, exhibiting constricted emotions, difficulty concentrating, autonomic disturbances, and reenactment of the trauma through play or action (see Chapters 1 and 25). Although young children may not fully meet these criteria, certain behavioral changes are commonly associated with exposure to trauma, such as sleep disturbances, aggressive behavior, new fears, and increased anxiety about separations ("clinginess"). A particular challenge in treating and diagnosing pediatric PTSD is that a child's caregiver exposed to the same trauma may be suffering from it as well.

Diagnosis and Follow-up

The simplest way to recognize whether violence has become a problem in a family is to screen both the parents and the children (after ≈8 yr of age) on a regular basis. This practice is particularly important during pregnancy and the immediate postpartum period when women may be at highest risk for being abused. It is important to assure families that they are not being singled out, but that all families are asked about their exposure to violence. A direct approach may be useful: "Violence is a major problem in our world today and one that impacts everyone in our society. Thus I have started asking all my patients and families about violence that they are experiencing in their lives. …" In other cases, beginning with general questions and then moving to the specific may be helpful. "Do you feel safe in your home and neighborhood? Has anyone ever hurt you or your child?" When violence has impacted the child, it is important to gather details about symptoms and behaviors.

The pediatric clinician can effectively counsel many parents and children who have been exposed to violence. Regardless of the type of violence to which the child has been exposed, the following components are part of the guidance: careful review of the facts and details of the event, gaining access to support services, providing information about the symptoms and behaviors common in children exposed to violence, assistance in restoring a sense of stability to the family in order to enhance the child's feelings of safety, and helping parents talk to their children about the event. When the symptoms are chronic (>6 mo in duration) or not improving, if the violent event involved the death or departure of a parent, if the caregivers are unable to empathize with the child, or if the ongoing safety of the child is a concern, it is important that the family be referred to mental health professionals for additional treatment.

Bibliography is available at Expert Consult.

39.1 Bullying, Cyberbullying, and School Violence

Douglas Vanderbilt and Marilyn C. Augustyn

BULLYING ("TRADITIONAL BULLYING")

Bullying is the assertion of power through social, emotional, or physical means of aggression that involves a bully repeatedly and intentionally targeting a weaker victim. Bullying affects a large number of children and lays the groundwork for long-term depression, suicidality, psychotic symptoms, conduct problems, and psychosomatic concerns seen in children. Children can move between being a bully, victim, bully-victim (both a bully and a victim at different times), or bystander. Bullying can be **direct,** involving physical aggression such as hitting, stealing, and threatening with a weapon or verbal aggression such as name-calling, public humiliation, and intimidation, or it can be **indirect,** involving relational aggression such as spreading rumors, social rejection, exclusion from peer groups, and ignoring. Bullying occurs most frequently at school when there is minimal supervision during breaks, recess, and lunch at playgrounds, in hallways, and en route to and from school.

CYBERBULLYING

Cyberbullying is an emerging form of bullying that takes place using electronic technology (text messaging, mass emailing, Internet chat rooms, social networking sites, etc.). In contrast to traditional bullying, it allows complete anonymity to the bully and has enormous capacity for "reach." Given its recent recognition and ongoing evolution, much remains unknown about its causes and therefore prevention strategies; what is clear is that the psychological consequences can be devastating for the victim. Victims of cyberbullying may be at higher risk for suicide (see Chapter 27) than victims of traditional bullying.

Epidemiology

Bullying is a common occurrence for schoolchildren. Bullying occurs in all countries, affecting anywhere from 9-54% of youth. Apparent rates of bullying are influenced by the manner in which questions are asked; youth are more willing to acknowledge having engaged in activities which can be categorized as forms of "bullying" than they are to respond to a question asking them if they have acted in a bullying manner or have been a bully.

The 2011 Indicators of School Crime and Safety reported that 28% of youth (31% females and 25% males) ages 12 to 18 yr had been bullied at school, 18% were ridiculed, 18% were the subject of rumors, 9% were cyberbullied, 8% were purposefully pushed, shoved, or tripped (leading to injury in about 1/5), 6% were purposefully excluded from activities, 5% were threatened with harm, and 3% had personal property that had been purposefully destroyed.

With regard to traditional bulling, the 2009 Youth Health Risk Behavior Survey (YHRBS), concurred that males and females were equally likely to report having been bullied (victims); males were 2.5 times more likely than females to report having bullied others. Rates of bullying or being bullied did not differ by race/ethnicity, except that Hispanics were less likely to report having bullied someone. Other surveys have found that students who carry weapons, smoke, and drink alcohol more than 5-6 days/wk were at greatest risk for moderate bullying. Those who carry weapons, smoke, have more than 1 alcoholic drink per day, have above-average academic performance, moderate/high family affluence, and feel irritable or bad-tempered daily were at greatest risk for frequent bullying. Negative parenting behavior is related to a moderate increase of risk for becoming a bully/victim and small to moderate effects on victim status at school.

Rates of cyberbullying victimization have ranged from 4-72% and of cyberbullying from 3-23%, in part reflecting variations in definitions and sampling design. According to the 2009 YHRBS, males and females were equally likely to experience cyberbullying, but males were >3-fold likely to report having been a cyberbully. Rates of cyberbullying (as victim or perpetrator) did not differ by race/ethnicity. Seniors were more likely to be involved in cyberbullying than youth in other grades.

A separate study conducted among 918 students in grades 6 through 12, found considerable overlap between traditional and cyberbullying/victimization; three-fourths were not involved as victim or bully in either traditional or cyberbullying. Most victims of traditional bullying were not involved in cyberbullying, but those with involvement were more likely to be victims. Most traditional bullies were not involved in cyberbullying but those who were, were generally bullies.

Health Outcomes

Involvement in bullying is associated with poorer psychosocial adjustment; bullies, victims, and bully-victims report greater health problems and poorer emotional and social adjustment. Victims tend to be either physically weak and emotionally vulnerable or provocative, with attention or conduct problems and have lower social status and higher social marginalization and isolation. Overall, **both** victim and

National Child Traumatic Stress Network http://www.nctsn.org/.

bully-victims have been described as anxious, insecure, lonely, and lacking social skills. They may have learning disabilities, autism spectrum disorder, or poor physical skills. They have more depression, psychosomatic complaints, medication use, and suicidality. Chronic or severe victimization in childhood has been shown to be associated with psychotic symptoms in early adolescence. Long-term consequences in adulthood of being bullied as a child include depression, poor self-esteem, and abusive relationships. In the 2009 YHRBS, traditional bullying victimization was a significant predictor of depression for males and females and a direct contributor to suicidal behavior for females.

Bullies have higher rates of both conduct disorders and social standing. They have the lowest rates of adjustment problems because of their higher social status. They make friends that support their bullying behavior but other peers avoid them. Bullies who acknowledge their behavior have higher rates of depression and psychologic distress compared to those who deny their bullying behavior. In the 2009 YHRBS data, traditional bullying predicted depression in females but not in males. Depression significantly mediated the relationship between bullying and suicidal behavior among both genders. They have higher negative attitudes toward school and use more tobacco, alcohol, and other drugs. Childhood bullies have a 4-fold increase in criminal behavior by their mid-20s and are at higher risk of dropping out of school. They have lower likelihood of being employed and having stable long-term romantic relationships. The bully-victim has problems with peer relationships and high rates of depression, loneliness, alcohol use, and weapon carrying.

Less is known about the characteristics of cyber bullies or victims and their long-term consequences. In the 2009 YHRBS data, cyber victimization was associated with depression in women but not men, and contributed to suicidal behavior among women. Cyberbullying was not associated with depression among men or women. Lower academic achievement and lower self-esteem are associated with cyberbullying perpetration and victimization, and anxiety symptoms with cyberbullying perpetration.

SCHOOL VIOLENCE

Epidemiology

School violence is a common but nonnormative aspect of development occurring throughout the world. Almost 40% of U.S. schools report a least 1 violent incident to police, with more than 600,000 victims of violent crime per year. Among 9th to 12th graders, 8% were threatened or injured on school property in the last 12 mo, and 14% were involved in a physical fight over the last year. School-associated violent deaths are rare. Seventeen homicides of children ages 5-18 yr occurred at school during the 2009-2010 school year. Of all youth homicides, less than 2% occur at school. These are more likely to occur at the beginning of each semester with perpetrators previously giving warning signals. Whereas urban schools experience more episodes of violence, the episodes of rare "rampage" gun violence in rural and suburban schools demonstrate that no region is immune to lethal violence.

Risk Factors

Bullying and weapon carrying may be important precursors to more serious school violence. Among perpetrators of violent deaths at school, 20% had been bullying victims, and 6% of all students carried a weapon to school in the last 30 days. Nonlethal violence, mental health problems, racial tensions, student attacks on teachers, and the effects of rapid economic change in communities can all lead to school violence. Individual risk factors for violence include prior history of violence, drug, alcohol, or tobacco use, association with delinquent peers, poor family functioning, poor grades in school, and poverty in the community.

Family risk factors include early childbearing, low parental attachment and involvement, authoritarian or permissive parenting styles, and poverty. There is more school violence in areas with higher crime rates and more street gangs, with little improvement with additional security measures. These risks take away students' ability to learn in a safe environment and leave many children with traumatic stress and grief reactions. Behavioral genetics and developmental psychology are beginning to elucidate the bidirectional gene-environment interactions that promote these endemic episodes of violence.

TREATMENT AND PREVENTION OF BULLYING AND SCHOOL VIOLENCE

Pediatric providers are in a unique position to screen, treat, and advocate for reducing the impact of school violence by assisting those affected and seeking to prevent further occurrences. **Signs** of a child being bullied include physical complaints such as insomnia, stomachaches, headaches, and new-onset enuresis (see Chapter 23.3). **Psychologic symptoms,** such as depression (see Chapter 26), loneliness, anxiety (see Chapter 25), and suicidal ideation, may occur. **Behavioral changes,** such as irritability, poor concentration, school avoidance, and substance abuse, are common. **School problems,** such as academic failure, social problems, and lack of friends, can also occur. Additional vigilance must be made for those children with chronic medical illnesses, obesity, physical deformities, and learning disabilities or autism spectrum disorder who may be potential targets. A bully may be more difficult to identify because of the bully's desire to obscure the behavior. Children who are aggressive, overly confident, lacking in empathy, and having conduct problems may need careful screening. The physical, behavioral, psychologic, and school symptoms of bullying may overlap with other conditions such as medical illness, learning problems, and psychologic disorders.

Simple questions to ask children include **BORRIS**: Have you been **bullied** or bullied anyone? Have you **observed** bullying going on? How did you **respond**? Do you feel like you are **repetitively** singled out as a bully or a victim? Have you sent or receiving things over the **Internet** that you think may represent bullying? Do you feel **stuck** in bullying situations? And for parents **WART**: Have you **witnessed** or heard about your child being picked on or picking on other kids? Have there been any recent changes about your child's **attitude,** attention and concentration changes? What are your community **rules** about bullying? Has your child **talked** to you about being picked on or witnessing other kids being picked on?

Management of bullying and school violence involves systemic interventions with parents, victims, bullies, and the school. Interventions should include supporting families, victims, and bullies; identifying and referring those children in need of further academic and mental health services; and expecting behavioral change from the bully and social change from the school environment. The clinician should listen empathetically to the child to help empower and reassure the child. The clinician should not blame the victim or trivialize the child's concern. Suggestions should include having the child seek social support from teachers and friends and avoiding situations where the bullying may occur. Role-playing an encounter can be helpful for the child. Extracurricular activities, like drama clubs, mentoring programs, and sports, can be used to help to bolster the child's self-esteem. The clinician should identify safety issues, such as suicidal ideation and plans, substance abuse, and other high-risk behaviors.

Once a bully is identified and appropriate screening for family risk factors is completed, the clinician should educate the parents and child about the seriousness of the behavior and its potential consequences. The clinician should label the behavior as the problem and help the family and child to acknowledge the behavior as hurtful. For example: "Do you feel bad when other children hurt your feelings?" "Bullying hurts other children's feelings." The school and parents should ensure accountability for the child's subsequent behavior. Parental mental health and resource risk factors should also be addressed.

Beyond individual- and family-based interactions, providers also can advocate for systemic interventions through **school-community violence and bullying prevention programs**. Targeted school curriculums or social skills group interventions have not been found to reduce bullying in several well-done studies. Successful interventions involve whole school approaches that involve multiple disciplines. These broad-based programs simultaneously include school-wide rules and

sanctions, teacher training, classroom curriculum, conflict resolution training, and individual counseling. Mentoring programs and an increased number of social workers can also be helpful in reducing bullying. Addressing access to firearms, involving community organizations and parents, enhancing the built environment of schools and community, and supporting youth self-esteem are important in creating a safe school climate. Targeting larger societal risk promoters of violence in the neighborhood and school culture are also avenues for improving school violence. In Denmark, an intensive national-level policy has led to the reduction in school bullying prevalence from 25% to 11%.

Prevention programs for cyberbullying are at a more nascent stage, reflecting uncertainty about the prevalence of the practice, who is perpetrating it and from where, and how students respond when they are victimized. One study of approximately 800 parents and 1200 of their children found that although 80% of parents had set rules regarding conduct on the Internet, 85% of the children who had engaged in cyberbullying had done so from their homes. Therefore, if the bullying is reported to the police, the police could track the IP address to find the bully. However, rates vary tremendously by survey (and country) regarding student notification of adults when cyberbullied, with less than 10% of students in a Swedish survey, one-third in a Canadian survey, and a majority in an Austrian survey having reported the victimization to an adult. Many schools have established cyberbullying policies and are increasingly involved with teaching youth about guidelines for appropriate online interactions, and monitoring for cyberbullying problems. As of July 2013, 49 states (plus Washington, DC) have enacted legislation aimed to prevent bullying and 47 states (plus Washington, DC) have specific legislation regarding electronic harassment. Pediatric clinicians must be aware of local legislative action to support children in this difficult topic. (See http://www.cyberbullying.us/Bullying_and_Cyberbullying_Laws.pdf)

Bibliography is available at Expert Consult.

39.2 Effects of War on Children

Isaiah D. Wexler and Eitan Kerem

The adverse consequences of war on children are endless—death, pain, dismemberment and other physical and cognitive disabilities, acute and chronic psychological suffering, temporary and permanent loss of family members, rape, conscription into armed service, forced relocation, famine, drought, and a litany of other untoward consequences lasting for decades after hostilities have ceased. More than 1 billion children <18 yr live in countries involved in war. The majority of sexual victims in war-torn nations are <17 yr of age. The United Nations Children's Fund (UNICEF) estimates that of the 3.6 million people killed as a result of military conflict between the years 1990 and 2003, 90% were civilian and 50% were children.

Mortality and morbidity related to the long-term effects of war and civil strife are often higher than that occurring during actual fighting. War and violence are not listed as leading causes of childhood mortality, but the regions with the highest levels of child mortality, especially among children <5 yr of age, are the same locations involved in military conflicts. Nations, especially but not limited to the least developed, devote substantial portions of their budgets to military expenditures at the expense of the healthcare infrastructure; a substantial proportion of deaths attributed to malnutrition, environmentally related infectious disease, or inadequate immunization are related to the effects of war. For example, an analysis of postwar (2003) Iraq found that mortality rates were 5.5/1,000/yr preinvasion (occurred in March 2003), and 13.2/1,000/yr for the 40 mo postinvasion; through mid-2006, there had been an estimated 654,965 fatalities above the preinvasion death rate, of which 601,027 were from violent causes. The largest group of deaths among females occurred among those <15 yr; infant and <5 yr of age mortality rates had not returned to their 1991 pre-Gulf War levels.

Table 39-2 Impact of War on Children
PHYSICAL
Death
Rape
Injuries
Amputations and fractures
Head trauma
Ballistic wounds
Blast injuries
Burns
Chemical and biologic induced
Malnutrition and starvation
Infectious disease
Displacement
PSYCHOSOCIAL
Loss of caregivers and family members
Separation from community
Lack of education
Inappropriate socialization
Acute stress reaction
Posttraumatic stress disorder
Depression
Maladaptive behavior
EXPLOITATION
Conscription as soldiers
Coerced involvement in terrorist activities
Prostitution
Slavery
Forced adoption

During wartime, customary patterns of behavior are forced to change, overcrowding is frequent, and essential resources, such as water and food staples, may be polluted or contaminated. War is associated with plagues and epidemics and novel disease entities can develop or reemerge. African nodding disease, Konzo (cassava-associated cyanide intoxication), polio, and other epidemics have been attributed to the effects of war.

The morbidity of children exposed to conflicts is significant (Table 39-2). Many more children are physically harmed than killed. Children bear the psychological scars of war resulting from exposure to violent events, loss of primary caregivers, and forced removal from their homes. During periods of war, children are more susceptible to exploitation in the forms of forced conscription as soldiers, sexual exploitation, and slavery. There are approximately 300,000 soldiers younger than the age of 18 yr who are actively participating in military conflicts worldwide. Lacking the appropriate education and socialization, the moral compass of these children is often misaligned. They are not capable of understanding the sources of conflict or why they have been targeted. Their thought processes are more concrete; it is easier for them to dehumanize their adversaries. Children, who themselves are exposed to violence and cruelty, often become the worst perpetrators of atrocities.

After cessation of hostilities, children are still at risk for life-endangering injuries from landmines and unexploded ordnance. Prior to the signing of the international treaty to ban landmines in 1997, an estimated 20,000-25,000 casualties occurred annually from landmines. In 1999, that number had decreased to 8,807 and by 2011 to 4,286. The CDC reported for a 5 yr period ending in 2006 that of the 5,741 individuals who were killed or injured by landmines or unexploded ordnance, 47.2% were children younger than the age of 18 yr. Injuries and death tended to occur while children were either playing or involved in household chores, and in contrast to adults, a large proportion of the injuries involved upper-extremity amputation. After the end of armed conflict, the continued proliferation of small arms and light weapons, which are easily handled by children, continues to take its toll on human life and hinders stabilization in postconflict societies.

SUSCEPTIBILITY OF CHILDREN IN TIMES OF WAR

Children do not have the physical or intellectual capabilities to defend themselves. It is easier for adults to victimize children than to victimize other adults. Older children's curiosity, desire for adventure, and imperfect assessment of risk often lead them to participate in dangerous behavior. Younger children, because of their small size and immature physiology, are more susceptible to disease and starvation, and are more likely to sustain fatal injuries from ballistic projectiles and explosive devices such as mines. Blast injuries, which are now the most common cause of battle-related injuries, have a more devastating impact on children as compared to adults. Specific types of military engagement can have a disproportionate effect on children. In a survey of war-related mortality in Iraq from 2003-2008, it was found that approximately 10% of the violence-related fatalities were children. Most children succumbed to either small-arms gunfire or suicide bombs (35%). When compared to adults, a proportionately higher rate of children died as a result of the usage of indiscriminant types of weaponry such as mortars, missiles, and aircraft-delivered bombs; 40% of the total casualties in these types of attacks were children.

During times of war, there is a breakdown of social inhibitions and cultural norms. Aberrant behavior such as rape, torture, and pillaging, which would be nearly inconceivable in times of peace, is common during war. Children may be attacked or used as human shields.

The changing nature of war has adversely affected children. Conventional warfare in which armies of professional soldiers representing different countries battle each other has become less common. Intrastate conflicts in the form of civil war are more frequent. Of the approximately 200 armed conflicts occurring after World War II, three-quarters have been intrastate. These conflicts are often rooted in ethnic or religious differences, and the participants are frequently nonprofessional "irregulars" who lack discipline and accountability to higher echelons, and are directed by those who do not acknowledge or respect international accords governing warfare. Often the military resources of the antagonists are disproportionate, leading the weaker protagonist to develop compensatory tactics that can include guerrilla, paramilitary, and terrorist activities, while the stronger side often resorts to the disproportionate use of force. Low-intensity conflicts have become more common. These types of conflicts are often characterized by military activities targeting civilian populations with the goal of disrupting normal routines and generating publicity for the perpetrators. Children are often victims, as this serves to maximize the impact of terrorist activity.

Terrorism and organized urban-based gang warfare violence have become more prevalent. Violence perpetrated by terrorists groups or gangs is designed to coerce and/or intimidate both individuals and entire societies. The destruction of the New York City World Trade Center Towers in 2001 and the nearly 3,000 fatalities showed that highly organized and motivated terrorists have few inhibitions and can strike anywhere. Biologic and chemical terrorism have also been realized, with the most recent example being the use of sarin gas, a deadly volatile nerve agent, in the Syrian civil war. Children are more susceptible to chemical and biologic toxins because of their higher respiratory rates, more permeable skin, and other developmental vulnerabilities (see Chapter 723).

The media has had a significant role in exacerbating the effects of war on children. Media coverage of war and terrorist events is extensive and graphic. Children, who are more impressionable than adults, often view this material in an uncontrolled fashion. Uncensored pictures of victims, unbridled violence, people in shock, or family members searching through ruins for relatives may traumatize children and even encourage inappropriate behavior. Overt broadcast propaganda glorifying war and violence may sway children to participate in militaristic or antisocial activities.

PSYCHOLOGIC IMPACT OF WAR

Exposure to war and violence can have a significant impact on a child's psychosocial development. Displacement, loss of caregivers, physical suffering, and the lack of appropriate socialization all contribute to abnormal child development (see Table 39-2). Often the reactions are age-specific (Table 39-3). Preschoolers may have an increase in somatic complaints and sleep disturbances, and have acting-out behavior such as tantrums or excessively clinging behavior. School-age children will show regressive behavior such as enuresis and thumb sucking. They, too, have an increase in somatic complaints; there is often a negative impact on school performance. For teenagers, psychological withdrawal and depression are common. Adolescents often exhibit trauma-stimulated acting-out behavior. Motivated by the desire for revenge, they may be quick to join in the violence and contribute to the continuation of conflict.

Table 39-3	Manifestations of Stress Reactions in Children and Adolescents Exposed to War, Terrorism, and Urban Violence
CHILDREN ≤6 YEARS	
Excessive fear of separation	
Clinging behavior	
Uncontrollable crying or screaming	
Freezing (persistent immobility)	
Sleep disorders	
Terrified affect	
Regressive behavior	
Expressions of helplessness and passivity	
CHILDREN 7-11 YEARS	
Decline in school performance	
Truancy	
Sleep disorders	
Somatization	
Depressive affect	
Abnormally aggressive or violent behavior	
Irrational fears	
Regressive and childish behavior	
Expressions of fearfulness, withdrawal, and worry	
ADOLESCENTS 12-17 YEARS	
Decline in school performance	
Sleep disturbances	
Flashbacks	
Emotional numbness	
Antisocial behavior	
Substance abuse	
Revenge fantasies	
Suicidal ideation	
Withdrawal	

There is an increased incidence of both acute stress reactions and PTSD (see Chapter 25). The true incidence is difficult to assess because of the heterogeneous nature of war, degree of exposure to violence, and methodological challenges related to the precise characterization of PTSD. The incidence of PTSD among children and adolescents living in Middle East countries that have experienced substantial armed conflict appear to be high: 5-8% in Israel, 23-70% in Palestine, and 10-30% in Iraq. Risk factors for having a more serious psychological response to a violent event include severity of the incident, personal involvement (physical injury, proximity, loss of a relative), prior history of exposure to traumatic events, female gender, and a dysfunctional parental response to the same event. It is not unusual for children to develop PTSD many years after the traumatic event. Children do not have to be directly exposed to violent activity, and media coverage of terrorist events may be sufficient to trigger PTSD.

The trauma experienced by children during war can have lifelong effects. Studies on children imprisoned in concentration camps or evacuated from their homes in London during the Battle of Britain show that these individuals were at greater risk for PTSD, anxiety disorders, and a higher level of dissatisfaction with life. Individuals who suffered wartime trauma can pass on certain traits to their children, including a greater propensity for PTSD. However, children are resilient. With appropriate support from family and community

together with timely and intensive psychological intervention, children can recover and lead normal, productive lives despite the searing trauma that they may have experienced.

EFFORTS TO PROTECT CHILDREN FROM THE EFFECTS OF WAR

International Conventions

War and terror violate the human rights of children, including the right to life, the right to be nurtured and protected, the right to develop appropriately, the right to be with family and community, and the right to a healthy existence. Several international treaties and conventions have been ratified, beginning with the **Fourth Geneva Convention** (1949) that set forth guidelines regarding appropriate treatment of children in times of war. The **United Nations Convention on the Rights of the Child** (1990) delineated specific human rights inherent to every child (defined as any individual younger than the age of 18 yr), and the subsequent **First Optional Protocol** (2000), which prohibits conscripting or recruiting children for military activities. **The Rome Statute of the International Criminal Court,** which was enacted in 2002, declared that the conscription or enlistment of children younger than the age of 15 yr is a prosecutable war crime. As of 2010, a decade since their passage, the number of armed conflicts in which children were serving as soldiers had decreased from 36 to 16 worldwide.

Although these treaties and conventions define the extent of protection afforded to children, the means of enforcement available to the international community is limited. Individuals, motivated by religious fervor, nationalistic zeal, or ethnic xenophobia, are unlikely to curb their activities because of fear of prosecution. These treaties better serve in heightening awareness regarding the protected status of children in wartime, and perhaps deter high-ranking leaders who fear being held accountable for war crimes.

Humanitarian Efforts

Several organizations, either nongovernmental or under the auspices of the United Nations, are involved in mitigating the effects of war on children. These organizations, which include the International Red Cross, UNICEF, United Nations Refugee Agency (UNCHR), International Rescue Committee, World Health Organization, and Médicins Sans Frontières (Doctors Without Borders), have had a significant impact on reducing violence-related casualties in war-torn regions. The infusion of humanitarian aid into developing countries often improves overall mortality and morbidity by increasing the level of medical and social services available to the general population. Other organizations, such as Amnesty International, Stockholm International Peace Research Institute, and Physicians for Human Rights, actively monitor human rights abuses involving children and other civilian groups. In 2005, the United Nations Security Council approved the establishment of a monitoring and reporting system designed to protect children exposed to war. United Nations–led task forces conduct active surveillance in war-stricken regions reporting on the *6 grave violations against children during armed conflict:* the killing or injuring of children, recruitment of child soldiers, attacks directed against schools or hospitals, sexual violence against children, abduction of children, and denial of humanitarian access for children.

THE ROLE OF PEDIATRICIANS AND ALLIED HEALTH PROFESSIONALS

War is a chronic condition and health providers need to be prepared to treat childhood casualties resulting from military or terrorist activity as well as caring for children suffering from the aftermath of war or related violence. Community and hospital pediatricians need to be involved in community disaster planning. General disaster planning should not ignore the unique needs and requirements of children; in planning for a possible chemical attack, appropriate resuscitation equipment suitable for children needs to be stockpiled. The signs of biologic infection or chemical intoxication are different for children, and pediatricians and emergency personnel need to be aware of these differences (see Chapters 719 and 723). Surveys of pediatricians and other healthcare providers indicate that many feel unprepared for bioterrorism attacks. Professional organizations such as the American Academy of Pediatrics and the CDC have published position papers; there is a special section in the American Academy of Pediatrics *Red Book* that presents guidelines for treating specific pathogens likely to be utilized in biologic warfare. In regions where violent terrorist activity is likely, pediatricians, nurses, and rescue personnel should consider becoming certified in the Red Cross Basic and Advanced Trauma Life Support.

Pediatricians need to be cognizant of the effects that war and terror can have on parents and children. Parents, who themselves are under tremendous strain, may not be sensitive to the effects that the same stressors have on their children. Pediatricians should draw out both parents and children, and encourage them to talk freely about their feelings. Child healthcare providers can be instrumental in educating parents to be more aware of inappropriate responses by children to war and violence. When necessary, pediatricians can serve their families by referring them to appropriate support services.

Just as it is important to administer first aid for physical trauma, it is also critical to provide psychologic first aid to victims of trauma. An excellent source of online information for both providers and caregivers is provided by the National Child Traumatic Stress Network (www.nctsn.org). In day-to-day patient interactions, a pediatrician is most likely to confront situations related to stress reactions such as PTSD or depressive disorders. Recognition of PTSD is essential so that early treatment can be initiated. *Diagnostic and Statistical Manual of Mental Disorders (DSM-5)* stipulates that for a diagnosis of PTSD, there has to be manifestations from each of four symptom clusters: intrusion, avoidance, negative alterations in cognitions and mood, and alterations in arousal and reactivity. The DSM-V also established a special preschool subtype of PTSD which has the same four symptom clusters but with specific manifestations that are typical of preschoolers exposed to trauma (see Chapter 25). Clues to the presence of PTSD and acute anxiety reactions include changes in behavior, school performance, affect, and sleep patterns, and an increase in somatic complaints. Even when the triggering event is neither temporally nor physically proximate, it should not dissuade the pediatrician from making an appropriate referral to mental health professionals who are expert in childhood stress disorders.

Medical professional standards demand from each physician that the physician treat all patients equitably without regard to their background. Both international law and professional medical societies ban physicians from actively participating in torture or other activities that infringe on human rights, including those of children. It is difficult to countenance any situation in which a health professional, even acting as a representative of his or her country, might directly or indirectly injure a minor.

Health professionals have an important role in preventing the atrocities that occur to children. In their role as advocates for the rights of children, pediatricians can be instrumental in focusing public attention on the precarious situation of children exposed to brutality and mayhem that are part and parcel of organized violence. They can promulgate the message that war and terror should not be allowed to rob children of their childhood.

Chapter 40

Abused and Neglected Children

Howard Dubowitz and Wendy G. Lane

The maltreatment (including abuse and neglect) of children is a pervasive problem in nations throughout the world (Fig. 40-1), with short- and long-term physical and mental health and social consequences to the child, family, community, and society at-large. In addition to the child healthcare professionals' responsibility to identify maltreated children and help ensure their protection and health, they should assume vital roles related to prevention, treatment, and advocacy. Rates and policies vary greatly among nations and often within nations. Rates of maltreatment and provision of services are affected by the overall policies of the country, province, or state governing recognition and responses to child abuse and neglect. Two broad approaches have been identified: a child and family welfare approach, with a focus on the family as a whole, and a child safety approach, with the focus on the child perceived to be at risk. The United States has primarily had a child safety approach.

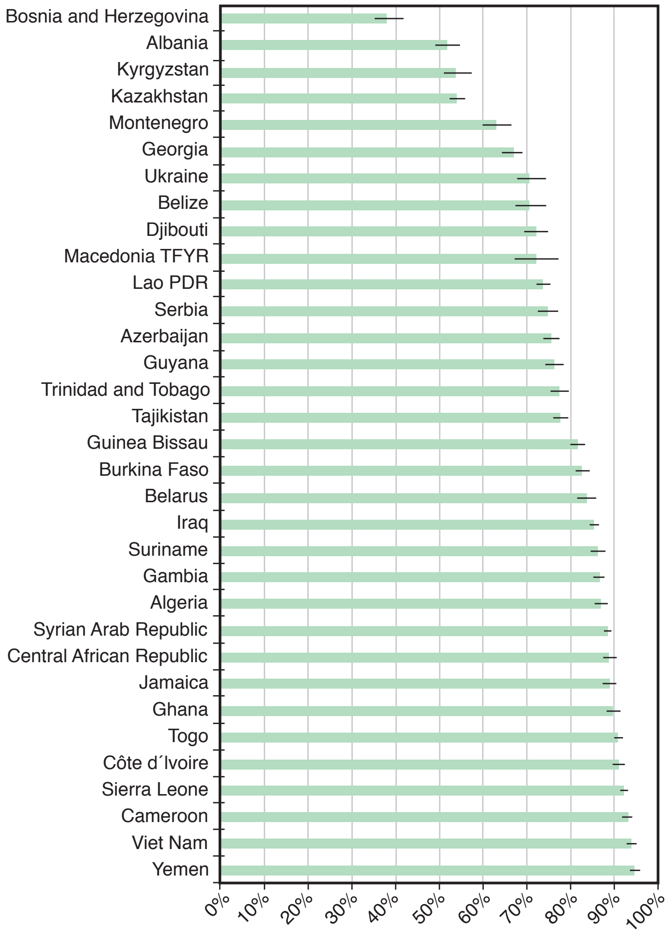

Figure 40-1 Percentage of children ages 2-14 yr who experienced any violent discipline (physical punishment and/or psychological aggression) in the past month, by country. *(From UNICEF,* Child disciplinary practices at home: evidence from a range of low- and middle-income countries, 2010. http://www.childinfo.org/discipline.html.*)*

DEFINITIONS

Abuse is defined as acts of commission and **neglect** as acts of omission. The U.S. government defines child abuse as "any recent act or failure to act on the part of a parent or caretaker, which results in death, serious physical or emotional harm, sexual abuse or exploitation, or an act or failure to act which presents an imminent risk of serious harm." Some states in the United States also include other household members. Children may be found in situations in which no actual harm has occurred and no imminent risk of serious harm is evident, but potential harm may be a concern. Many states include potential harm in their child abuse laws. Consideration of potential harm enables preventive intervention, although predicting potential harm is inherently difficult. Two aspects should be considered. One is the likelihood of harm; the other is the severity of that harm.

Physical abuse includes beating, shaking, burning, and biting. Corporal punishment in any form is increasingly being prohibited. The Global Initiative to End All Corporal Punishment of Children reported that 33 countries have prohibited corporal punishment in all settings, including the home. Governments in at least an additional 18 countries are publicly committed to prohibition in all settings. The majority of countries have prohibited corporal punishment in settings outside the home—in schools (117 countries), in penal institutions (121 countries), and as a sentence of the courts (157 countries). In the United States, corporal punishment in the home is lawful in all states, but 31 states have banned corporal punishment in public schools and the Supreme Court has ruled it unlawful as punishment for a crime.

Internationally, a high proportion of children continue to experience corporal punishment. At the beginning of 2013, 33 countries had banned all corporal punishment, while in 165 some form of corporal punishment is permitted, including 41 countries in which children can be sentenced to corporal punishment for committing a crime.

The threshold for defining corporal punishment as abuse is unclear. One can consider any injury beyond transient redness as abuse. If parents spank a child, it should be limited to the buttocks, should occur over clothing, and should never involve the head and neck. When parents use objects other than a hand, the potential for serious harm increases. Acts of serious violence (e.g., throwing a hard object, slapping an infant's face) should be seen as abusive even if no injury ensues; significant risk of harm exists. Although some child healthcare professionals think that hitting is acceptable under limited conditions, almost all believe that more constructive approaches to discipline are preferable. Although many think that hitting a child should never be acceptable, and many studies have documented the potential harm, there remains a reluctance in the United States to label hitting as abuse unless there is an injury. It is clear that the emotional impact of being hit may leave the most worrisome scar, long after the bruises fade and the fracture heals.

Sexual abuse has been defined as "the involvement of dependent, developmentally immature children and adolescents in sexual activities which they do not fully comprehend, to which they are unable to give consent, or that violate the social taboos of family roles." Sexual abuse includes exposure to sexually explicit materials, oral–genital contact, genital-to-genital contact, genital-to-anal contact, and genital fondling. Any touching of "private parts" by parents or caregivers in a context other than necessary care is inappropriate.

Neglect refers to omissions in care, resulting in actual or potential harm. Omissions include inadequate healthcare, education, supervision, protection from hazards in the environment, and unmet physical needs (e.g., clothing, food) and emotional support. A preferable alternative to focusing on caregiver omissions is to instead consider the basic needs (or rights) of children (e.g., adequate food, clothing, shelter, healthcare, education, nurturance); neglect occurs when a need is not adequately met and results in actual or potential harm, whatever the reasons. A child whose health is jeopardized or harmed by not receiving necessary care experiences medical neglect. Not all such situations

necessarily require a report to **child protective services (CPS)**; less-intrusive initial efforts may be appropriate.

Psychological abuse includes verbal abuse and humiliation and acts that scare or terrorize a child. Although this form of abuse may be extremely harmful to children, resulting in depression, anxiety, poor self-esteem, or lack of empathy, CPS seldom becomes involved because of the difficulty in proving such allegations. Child healthcare professionals should still carefully consider this form of maltreatment, even if the concern fails to reach a legal or agency threshold for reporting. These children and families can benefit from counseling and social support. Many children experience more than 1 form of maltreatment; CPS may be more likely to address psychological abuse in the context of other forms of maltreatment.

Internationally, problems of **trafficking** in children, for purposes of cheap labor and/or sexual exploitation, expose children to all of the forms of abuse just noted.

INCIDENCE AND PREVALENCE

Global Situation

Child abuse and neglect are not rare and occur worldwide. Based on international studies, the World Health Organization (WHO) has estimated that approximately 20% of women and 5-10% of men report being sexually abused as children, while 25-50% of all children report being physically abused. Many children experience emotional abuse and neglect. Rates of child abuse overall and both corporal and psychological vary greatly by this sample of lower- and middle-income nations. Although more difficult to detect and therefore probably underestimated, reports of psychological abuse tend to be somewhat higher than those of physical abuse (Fig. 40-2).

Situation in the United States

Abuse and neglect mostly occur behind closed doors and often are a well-kept secret. Nevertheless, there were 3.4 million reports to CPS involving 6.2 million children in the United States in 2011. Of the 681,000 children with substantiated reports, 78.5% experienced neglect, 17.6% physical abuse, 9.1% sexual abuse, and 9% psychological maltreatment. These rates of substantiated maltreatment continue a trend where neglect has remained at a steady rate since the early 1990s, whereas both sexual and physical abuse rates have declined by approximately 50%. Medical personnel made 8.4% of all reports. The rate of hospitalized children with serious physical abuse has *not* declined in recent years, raising the possibility of CPS trends not necessarily representing a true decline.

Etiology

Child maltreatment seldom has a single cause; rather, multiple and interacting biopsychosocial **risk factors** at 4 levels usually exist. To illustrate, at the *individual level*, a child's disability or a parent's depression or substance abuse predispose a child to maltreatment. At the *familial level*, intimate partner (or domestic) violence presents risks for children. Influential *community factors* include stressors such as dangerous neighborhoods or a lack of recreational facilities. Professional inaction may contribute to neglect, such as when the treatment plan is not clearly communicated. Broad *societal factors*, such as poverty and its associated burdens, also contribute to maltreatment. WHO estimates the rate of homicide of children is approximately 2-fold higher in low-income compared to high-income countries (2.58 vs. 1.21 per 100,000 population), but clearly homicide occurs in high-income countries. Children in all social classes can be maltreated, and child healthcare professionals need to guard against biases concerning low-income families.

Protective factors, such as family supports, or a mother's concern for her child, may buffer risk factors and protect children from maltreatment. Identifying and building on protective factors can be vital to intervening effectively. One can say to a parent, for example, "I can see how much you love ____. What can we do to keep her out of the hospital?" Child maltreatment results from a complex interplay among risk and protective factors. A single mother who has a colicky baby and who recently lost her job is at risk for maltreatment, but a loving

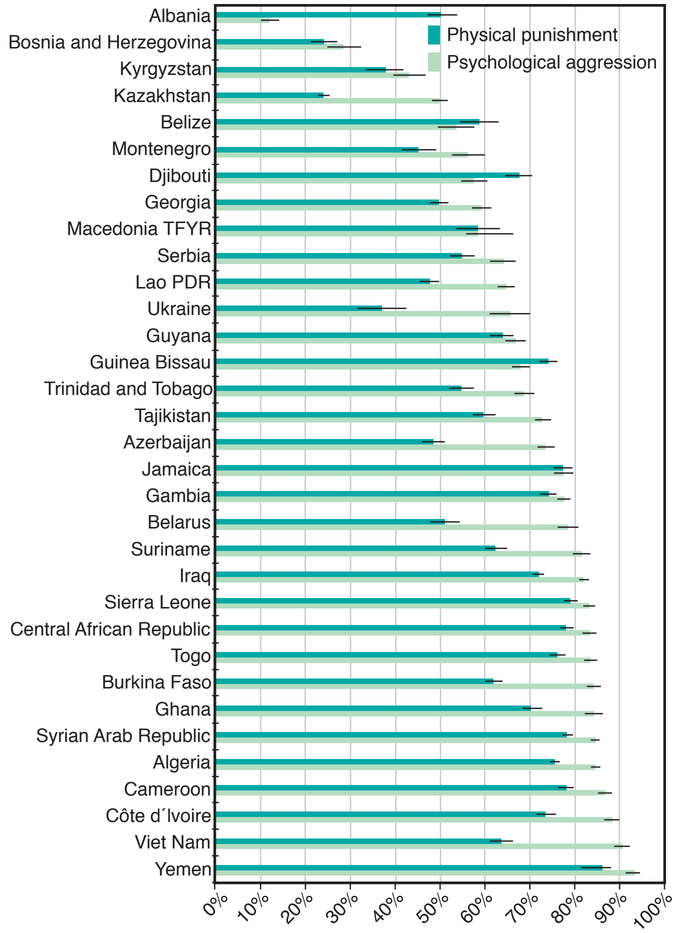

Figure 40-2 Percentage of children ages 2-14 yr who experienced psychological aggression and percentage of children ages 2-14 yr who experienced physical punishment in the past month, by country, 2005-2006. *(From UNICEF,* Child disciplinary practices at home: evidence from a range of low- and middle-income countries, 2010. http://www.childinfo.org/discipline.html.*)*

grandmother may be protective. A good understanding of factors that contribute to maltreatment, as well as those that are protective, should guide an appropriate response.

Clinical Manifestations

Child abuse and neglect can manifest in many different ways. With regard to physical abuse, a critical element is the lack of a plausible history other than inflicted trauma. Signs of abuse may precede the eventual diagnosis of child abuse. These **sentinel injuries** may be noted in approximately 25% of abused infants and may precede the diagnosis by weeks or even months from the sentinel event. Bruising and intraoral injury, in addition to symptoms of an acute life-threatening event, may be early clues of abuse. As with any medical condition, the onus is on the clinician to carefully consider the differential diagnosis and not jump to conclusions.

Bruises are the most common manifestation of physical abuse. Features suggestive of inflicted bruises include (a) bruising in a preambulatory infant (occurring in just 2% of infants), (b) bruising of padded and less-exposed areas (buttocks, cheeks, under the chin, genitalia), (c) patterned bruising or burns conforming to shape of an object or ligatures around the wrists (Table 40-1, Figs. 40-3 and 40-4), and (d) multiple bruises, especially if clearly of different ages. Earlier suggestions for estimating the age of bruises have been discredited. It is very difficult to precisely determine the ages of bruises.

Other conditions, such as birthmarks and mongolian spots can be confused with bruises and abuse. These skin markings are not tender

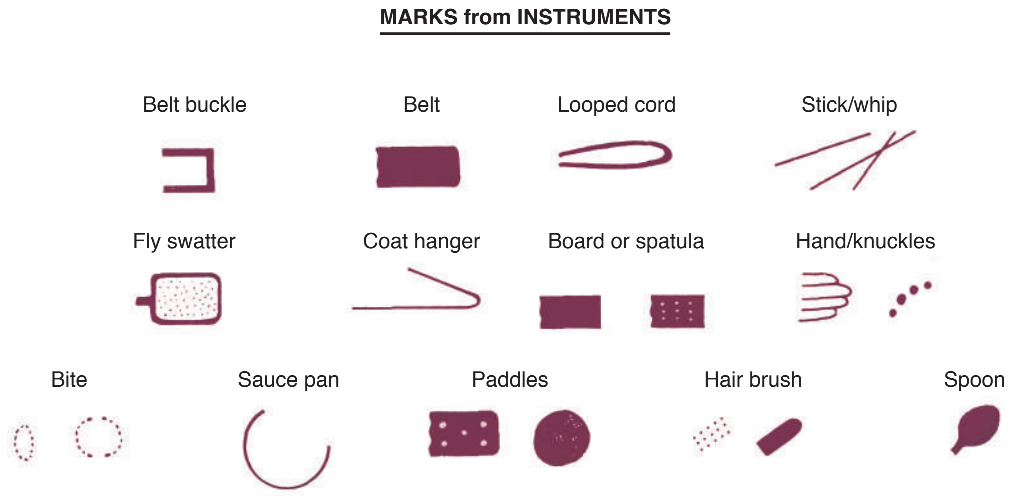

Figure 40-3 A variety of instruments may be used to inflict injury on a child. Often the choice of an instrument is a matter of convenience. Marks tend to silhouette or outline the shape of the instrument. The possibility of intentional trauma should prompt a high degree of suspicion when injuries to a child are geometric, paired, mirrored, of various ages or types, or on relatively protected parts of the body. Early recognition of intentional trauma is important to provide therapy and prevent escalation to more serious injury.

Table 40-1 Injury Patterns

METHOD OF INJURY/IMPLEMENT	PATTERN OBSERVED
Grip/grab	Relatively round marks that correspond with fingertips and/or thumb
Closed-fist punch	Series of round bruises that correspond with the knuckles of the hand
Slap	Parallel, linear bruises (usually petechial) separated by areas of central sparing
Belt/electrical cord	Loop marks or parallel lines of petechiae (the width of the belt/cord) with central sparing; may see triangular marks from the end of the belt, small circular lesions caused by the holes in the tongue of the belt, and/or a buckle pattern
Rope	Areas of bruising interspersed with areas of abrasion
Other objects/household implements	Injury in shape of object/implement (e.g., rods, switches, and wires cause linear bruising)
Human bite	Two arches forming a circular or oval shape, may cause bruising and/or abrasion
Strangulation	Petechiae of the head and/or neck, including mucous membranes; may see subconjunctival hemorrhages
Binding/ligature	Marks around the wrists, ankles, or neck; sometimes accompanied by petechiae or edema distal to the ligature mark Marks adjacent to the mouth if the child has been gagged
Excessive hincar (punishment by kneeling on salt or other rough substance)	Abrasions/burns, especially to knees
Hair pulling	Traumatic alopecia; may see petechiae on underlying scalp, or swelling or tenderness of the scalp (from subgaleal hematoma)
Tattooing or intentional scarring	Abusive cases have been described, but can also be a cultural phenomenon (e.g., Maori body ornamentation)

and do not rapidly change color or size. An underlying medical explanation for bruises may exist, such as connective tissue disorders or blood dyscrasias (see Chapters 476, 477, and 484). The history or examination usually provides clues to these conditions. Henoch-Schönlein purpura, the most common vasculitis in young children, may be confused with abuse. The pattern and location of bruises caused by abuse are usually different from those caused by a coagulopathy. Noninflicted bruises are characteristically anterior and over bony prominences, such as chin, ankles, elbows, shins, and forehead. The presence of a medical disorder does not preclude abuse.

Cultural practices can cause bruising. Cao gio, or *coining*, is a Southeast Asian folkloric therapy. A hard object is vigorously rubbed on the skin, causing petechiae or purpura. Cupping is another approach, popular in the Middle East. A heated glass is applied to the skin, often on the back. As it cools, a vacuum forms, leading to perfectly circular bruises. The context here is important, and such circumstances should not be considered abusive (see Chapter 4).

A careful history of bleeding problems in the patient and first degree relatives is needed. If a bleeding disorder is suspected, a complete blood count including platelet count, prothrombin time, and partial thromboplastin time should be obtained. More extensive testing, such as factors VIII, IX, and XI activity and a von Willebrand evaluation, should be considered in consultation with a hematologist.

Bites have a characteristic pattern of 1 or 2 opposing arches with multiple bruises (see Fig. 40-3). They can be inflicted by an adult, another child, an animal, or the patient. Bites by a child (younger than approximately 8 yr with primary teeth) typically have a distance of less than 2.5 cm between the canines—often the most prominent bruises.

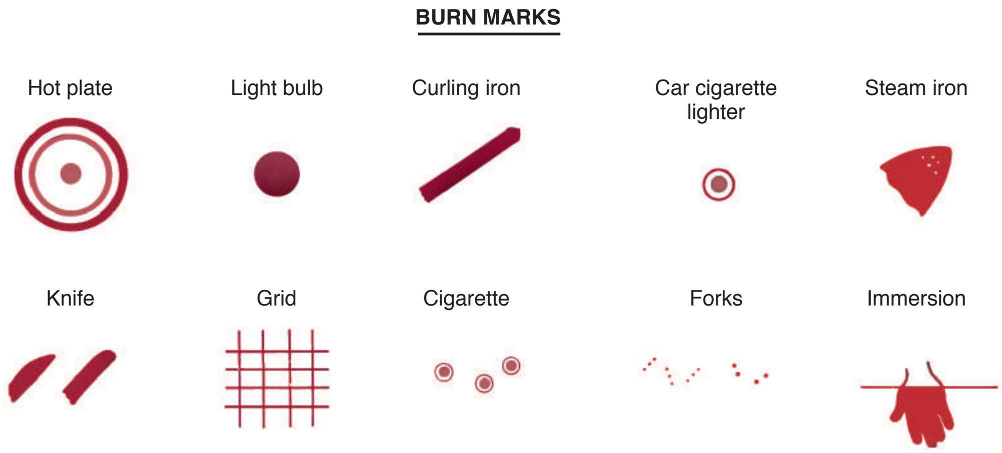

Figure 40-4 Marks from heated objects cause burns in a pattern that duplicates that of the object. Familiarity with the common heated objects that are used to traumatize children facilitates recognition of possible intentional injuries. The location of the burn is important in determining its cause. Children tend to explore surfaces with the palmar surface of the hand and rarely touch a heated object repeatedly or for a long time.

Figure 40-5 Immersion injury patterns. **A,** Sparing of the flexor creases. **B,** Immersion "stocking" burn. **C,** Immersion "glove" burn. **D,** Immersion buttocks burn. *(From Jenny C:* Child abuse and neglect: diagnosis, treatment, and evidence, *Philadelphia, 2011, Saunders, p. 225, Fig. 28-3.)*

The appearance of animal bites is variable; they usually have narrower arches than human bites and are often deep (see Chapter 724). Self-inflicted bites are on accessible areas, particularly the hands. Adult bites raise concern for abuse. Multiple bites by another child suggest inadequate supervision and neglect.

Burns may be inflicted or a result of inadequate supervision. Scalding burns may result from immersion or splash. Immersion burns, when a child is forcibly held in hot water, show clear delineation between the burned and healthy skin, and uniform depth. They may have a sock or glove distribution. Splash marks are usually absent, unlike when a child inadvertently encounters hot water. Symmetric burns are especially suggestive of abuse as are burns of the buttocks and perineum. Although most often accidental, splash burn may also result from abuse. Burns from hot objects such as curling irons, radiators, steam irons, metal grids, hot knives, and cigarettes leave patterns representing the object. A child is likely to try to rapidly escape from a hot object; thus burns that are extensive and deep reflect more than fleeting contact and are suggestive of abuse (Fig. 40-5).

Several conditions mimic abusive burns, such as brushing against a hot radiator, car seat burns, hemangiomas, and folk remedies, such as moxibustion. Impetigo may resemble cigarette burns. Cigarette burns are usually 7-10 mm across, whereas impetigo has lesions of varying size (see Chapter 665.1). Noninflicted cigarette burns are usually oval and superficial.

Neglect frequently contributes to childhood burns. Children, home alone, may be burned in house fires. A parent taking drugs may cause a fire and may be unable to protect a child. Exploring children may pull hot liquids left unattended onto themselves. Liquids cool as they flow downward so that the burn is most severe and broad proximally. If the child is wearing a diaper or clothing, the fabric may absorb the

hot water and cause burns worse than otherwise expected. Some circumstances are difficult to foresee, and a single burn resulting from a momentary lapse in supervision should not automatically be seen as neglectful parenting.

Concluding whether a burn was inflicted depends on the history, burn pattern, and the child's capabilities. A delay in seeking healthcare may result from the burn initially appearing minor, before blistering or becoming infected. This circumstance may represent reasonable behavior and should not be automatically deemed neglectful. A home investigation is often valuable (e.g., testing the water temperature).

Fractures that strongly suggest abuse include classic metaphyseal lesions, posterior rib fractures, and fractures of the scapula, sternum, and spinous processes, especially in young children (Table 40-2). These fractures all require more force than would be expected from a minor fall or routine handling and activities of a child. Rib and sternal fractures rarely result from cardiopulmonary resuscitation, even when performed by untrained adults. It is possible, however, that the recommended 2-finger or 2-thumb technique recommended for infants since 2005 may produce anterolateral rib fractures. In abused infants, rib (Fig. 40-6), metaphyseal (Fig. 40-7), and skull fractures are most common. Femoral and humeral fractures in nonambulatory infants are also highly suggestive for abuse. With increasing mobility and running, toddlers can fall with enough rotational force to cause a spiral, femoral fracture. Multiple fractures in various stages of healing are suggestive of abuse; nevertheless, underlying conditions need to be considered. Clavicular, femoral, supracondylar humeral, and distal extremity fractures in children older than 2 yr are most likely noninflicted unless they are multiple or accompanied by other signs of abuse. Few fractures are pathognomonic of abuse; all must be considered in light of the history.

Table 40-2 Skeletal Injuries from Abuse
High-specificity findings
• Classic metaphyseal corner lesions
• Posterior rib fracture
• Scapular fracture
• Sternal fracture
• Spinous process fracture
• First rib fracture
Moderate-specificity findings
• Multiple fractures
• Fractures of differing age
• Spine fracture
• Complex skull fracture
• Physeal fractures of the long bones
• Digital fractures
Low-specificity findings
• Diaphyseal fractures of the long bones
• Simple skull fractures
• Clavicle fracture

Modified from Kleinman PK. Diagnostic imaging of child abuse, *ed 2, St. Louis, 1998, Mosby.*

Figure 40-6 A high-detail oblique view of the ribs of a 6 mo old infant shows multiple healing posteromedial rib fractures (*arrowheads*). The level of detail in this image is far greater than what would be present on a standard chest radiograph. *(From Dwek JR: The radiographic approach to child abuse.* Clin Orthop Relat Res *469:776-789, 2011, p. 780, Fig. 4.)*

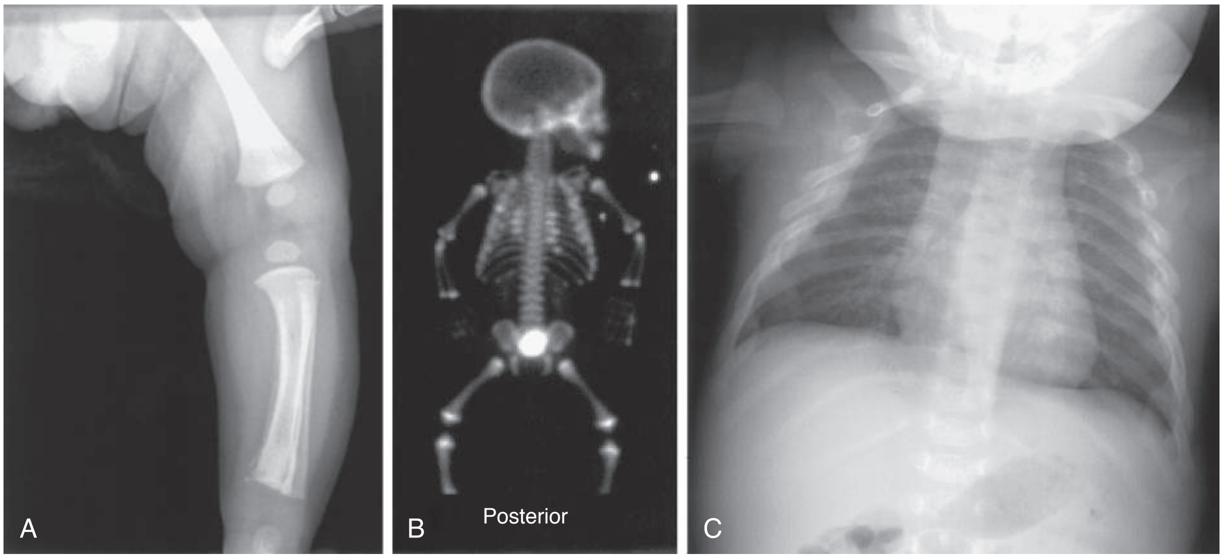

Figure 40-7 A, Metaphyseal fracture of the distal tibia in a 3 mo old infant admitted to the hospital with severe head injury. There is also periosteal new bone formation of the tibia, perhaps from previous injury. **B,** Bone scan of same infant. Initial chest x-ray showed a single fracture of the right posterior 4th rib. A radionuclide bone scan performed 2 days later revealed multiple previously unrecognized fractures of the posterior and lateral ribs. **C,** Follow-up radiographs 2 wk later showed multiple healing rib fractures. This pattern of fracture is highly specific for child abuse. The mechanism of these injuries is usually violent squeezing of the chest.

The *differential diagnosis* includes conditions that increase susceptibility to fractures, such as osteopenia of prematurity and osteogenesis imperfecta, metabolic and nutritional disorders (e.g., scurvy, copper deficiency, rickets), renal osteodystrophy, osteomyelitis, congenital syphilis, congenital insensitivity to pain, Caffey disease, and neoplasia. Some have pointed to possible rickets and low but subclinical levels of vitamin D as being responsible for fractures thought to be abusive. The evidence to date does not support this supposition. Features of congenital or metabolic conditions associated with nonabusive fractures include family history of recurrent fractures after minor trauma, abnormally shaped cranium, dentinogenesis imperfecta, blue sclera, wormian bones, craniotabes, ligamentous laxity, bowed legs, hernia, and translucent skin. Subperiosteal new bone formation is a nonspecific finding seen in infectious, traumatic, and metabolic disorders. In young infants, new bone formation may be a normal physiologic finding, usually bilateral, symmetric, and less than 2 mm in depth.

The evaluation of a fracture should include a skeletal survey in children <2 yr of age when abuse seems possible. Multiple films with different views are needed (Table 40-3); "babygrams" (1 or 2 films of the entire body) should be avoided. If the survey is normal, but concern for an occult injury remains, a radionucleotide bone scan should be performed to detect a possible acute injury. Follow-up films after 2 wk may also reveal fractures not apparent initially.

In corroborating the history and the injury, the age of a fracture can be crudely estimated (Table 40-4). Soft-tissue swelling subsides in 2-21 days. Periosteal new bone is visible within 4-21 days. Loss of definition of the fracture line occurs between 10-21 days. Soft callus can be visible after 10 days and hard callus between 14-90 days. These time frames are shorter in infancy and longer in children with poor nutritional status or a chronic underlying disease. Fractures of flat bones such as the skull do not form callus and cannot be aged, although soft-tissue swelling indicates approximate recency (i.e., within the prior week).

Abusive head trauma (AHT) results in the most significant morbidity and mortality. Abusive injury may be caused by direct impact, asphyxia, or shaking. Subdural hematomas (Fig. 40-8), retinal hemorrhages (Fig. 40-9), particularly when extensive and involving multiple layers, and diffuse axonal injury strongly suggest AHT, especially when they co-occur. The poor neck muscle tone and relatively large heads of infants make them vulnerable to acceleration–deceleration forces associated with shaking, leading to AHT. Children may lack external signs of injury, even with serious intracranial trauma. Signs and symptoms may be nonspecific, ranging from lethargy, vomiting (without diarrhea), changing neurologic status or seizures, and coma. In all preverbal children, an index of suspicion for AHT should exist when children present with these signs and symptoms. Asymptomatic subdural hemorrhage may occur after vaginal or cesarean birth. These resolve by 1 mo of age and prior to resolution the infant remains asymptomatic.

Skull fractures are common in abuse, reflecting impact injury. There is no specific pattern of skull fracture that is diagnostic of abuse. Acute intracranial trauma is best evaluated via initial and follow-up CT. MRIs are helpful in differentiating extra axial fluid, determining timing of injuries, assessing parenchymal injury, and identifying vascular anomalies. MRIs are best obtained 5-7 days after an acute injury. Glutaric aciduria type 1 can present with intracranial bleeding and should be considered. Other causes of subdural hemorrhage in infants include arteriovenous malformations, coagulopathies, birth trauma, tumor, or infections. When AHT is suspected, injuries elsewhere—skeletal and abdominal—should be ruled out.

Table 40-3 Skeletal Survey for Infants and Children Under 2 Yr of Age*

- Anteroposterior (AP) and lateral of skull (Townes view optional; add if any fracture seen)
- Lateral spine (C-spine may be included on skull radiographs; AP spine is included on AP chest and AP pelvis to include entire spine)
- AP, right posterior oblique, left posterior oblique of chest—rib technique
- AP pelvis
- AP of each femur
- AP of each leg
- AP of each humerus
- AP of each forearm
- Posteroanterior of each hand
- AP (dorsoventral) of each foot

*Images are checked by a radiologist before the patient leaves. Poorly positioned or otherwise suboptimal images should be repeated. Lateral views are added for positive or equivocal findings in the extremities. Coned views of positive or equivocal findings (i.e., at the ends of the long bones, ribs) may be obtained.

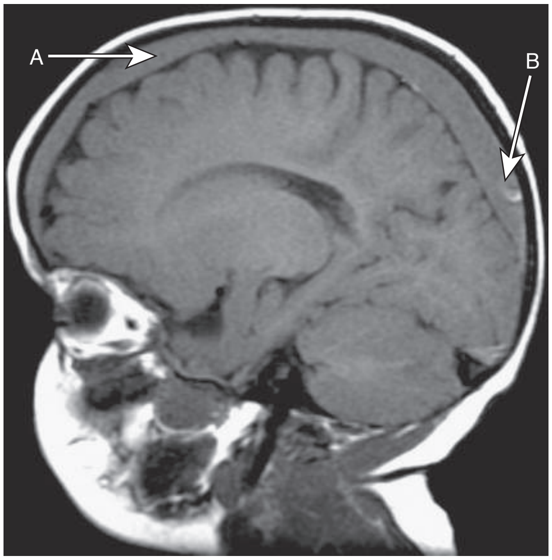

Figure 40-8 CT scan indicating intracranial bleeding. *A*, Older blood. *B*, New blood.

Table 40-4 Timetable of Radiologic Changes in Children's Fractures*

CATEGORY	EARLY	PEAK	LATE
1. Resolution of soft-tissue swelling	2-5 days	4-10 days	10-21 days
2. Subperiosteal new bone formation	4-10 days	10-14 days	14-21 day
3. Loss of fracture line definition, days		10-14 days	14-21 days
4. Soft callus		10-14 days	14-21 days
5. Hard callus	14-21 days	21-42 days	42-90 days
6. Remodeling of fracture	3 mo	1 yr	2 yr to physeal closure

*Repetitive injuries may prolong categories 1, 2, 5, and 6.

From Kleinman PK: Diagnostic imaging of child abuse, *ed. 2, St. Louis, 1998, Mosby, p. 176.*

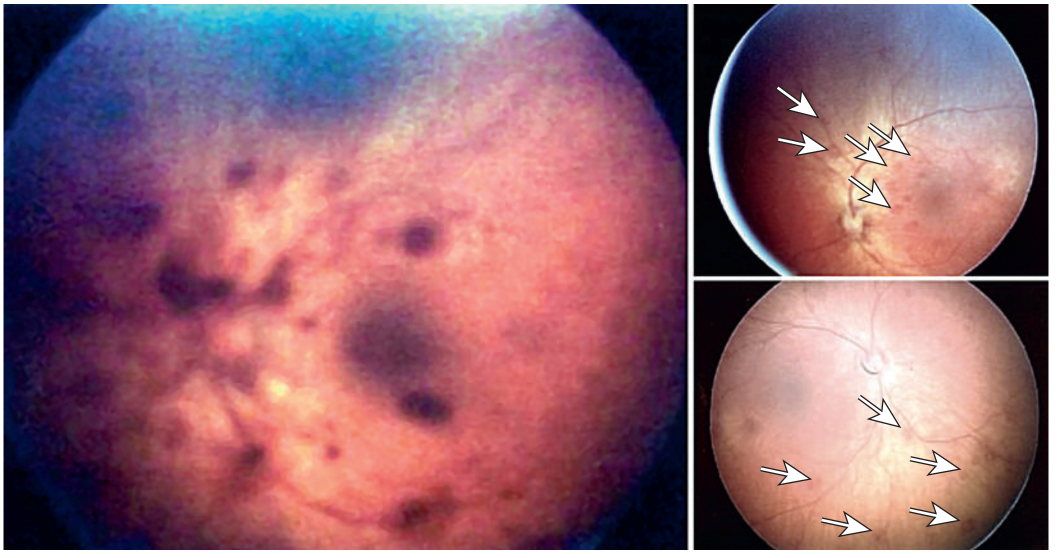

Figure 40-9 Retinal hemorrhages. Arrows point to hemorrhages of various sizes.

Retinal hemorrhages are an important marker of AHT (see Fig. 40-9). Whenever AHT is being considered, a dilated indirect eye examination by a pediatric ophthalmologist should be performed. Although retinal hemorrhages can be found in other conditions, hemorrhages that are multiple, involve more than one layer of the retina, and extend to the periphery (outside the posterior pole) are very suspicious for abuse. The mechanism is likely repeated acceleration–deceleration as a consequence of shaking. Traumatic retinoschisis points strongly to abuse.

There are other causes of retinal hemorrhages, although the pattern is usually different than that seen in child abuse. After normal spontaneous vaginal delivery, 25% of term neonates may have retinal hemorrhages (lower with caesarian section, higher with vacuum assisted delivery). These hemorrhages are in the posterior pole and are intraretinal; 80% resolve by 10 days, 100% by 6-8 wk. Coagulopathies (particularly leukemia), retinal diseases, carbon monoxide poisoning, or glutaric aciduria may be responsible. Severe noninflicted direct crush injury to the head can rarely cause an extensive hemorrhagic retinopathy. Cardiopulmonary resuscitation rarely, if ever, causes retinal hemorrhage in infants and children; if present, there a few hemorrhages in the posterior pole. Hemoglobinopathies, diabetes mellitus, routine play, minor noninflicted head trauma, and vaccinations do not appear to cause retinal hemorrhage in children. Severe coughing or seizures rarely cause retinal hemorrhages that could be confused with AHT. Retinal hemorrhages are rare in children with increased cranial pressure.

The dilemma frequently posed is whether minor, "everyday" forces can explain the findings seen in AHT. Simple linear skull fractures in the absence of other suggestive evidence can be explained by a short fall, although even that is rare (1-2%), and underlying brain injury from short falls is exceedingly rare. Timing of brain injuries in cases of abuse is not precise. In fatal cases, however, the trauma most likely occurred very soon before the child became symptomatic.

Other manifestations of AHT may be seen. "Raccoon" eyes occur in association with subgaleal hematomas after traction on the anterior hair and scalp or after a blow to the forehead. Neuroblastoma can present similarly, and should be considered (see Chapter 498). Bruises from attempted strangulation may be visible on the neck. Choking or suffocation can cause hypoxic brain injury, often with no external signs.

Abdominal trauma accounts for significant morbidity and mortality in abused children. Young children are especially vulnerable because of their relatively large abdomens and lax abdominal musculature. A forceful blow or kick can cause hematomas of solid organs (liver, spleen, kidney) from compression against the spine, as well as hematoma (duodenal) or rupture (stomach) of hollow organs. Intraabdominal bleeding may result from trauma to an organ or from shearing of a vessel. More than one organ may be affected. Children may present with cardiovascular failure or an acute condition of the abdomen, often after a delay in care. Bilious vomiting without fever or peritoneal irritation suggests a duodenal hematoma, often caused by abuse.

The manifestations of abdominal trauma are often subtle, even with severe injuries. Bruising of the abdominal wall is unusual, and symptoms may evolve slowly. Delayed perforation may occur days after the injury; bowel strictures or a pancreatic pseudocyst may occur weeks or months later. Child healthcare professionals should consider screening for occult abdominal trauma when other evidence of physical abuse exists. Screening should include liver and pancreatic enzyme levels, and testing urine for blood. Children with lab results indicating possible injury should have abdominal CT performed. CT or ultrasound should also be performed if there is concern about possible splenic, adrenal, or reproductive organ injury.

Neglect is the most prevalent form of child maltreatment, with potentially severe and lasting sequelae. It may manifest in many ways, depending on which needs are not adequately met. Nonadherence to medical treatment may aggravate the condition, as may a delay in seeking care. Inadequate food may manifest as impaired growth; inattention to obesity may compound that problem. Poor hygiene may contribute to infected cuts or lesions. Inadequate supervision contributes to injuries and ingestions. Children's needs for mental healthcare, dental care, and other health-related needs may be unmet, manifesting as neglect in those areas. Educational needs, particularly for children with learning disabilities, are often not met.

The evaluation of possible neglect requires addressing several critical questions. "Is this neglect?" "Have the circumstances harmed the child, or jeopardized the child's health and safety?" Suboptimal treatment adherence may lead to few or no clear consequences. Inadequacies in the care children receive naturally fall along a continuum, requiring a range of responses tailored to the individual situation. Legal considerations or CPS policies may discourage physicians from labeling many circumstances as neglect. Even if neglect does not meet a threshold for reporting to CPS, child healthcare professionals can still help ensure children's needs are adequately met.

GENERAL PRINCIPLES FOR ASSESSING POSSIBLE ABUSE AND NEGLECT

The heterogeneity of circumstances in situations of child maltreatment precludes specific details. The following are useful general principles.

- Given the complexity and possible ramifications of determining child maltreatment, an interdisciplinary assessment is optimal, with input from all involved professionals. Consultation with a physician expert in child maltreatment is recommended.

- A thorough history should be obtained from the parent(s) optimally via separate interviews.
- Verbal children should be interviewed separately, in a developmentally appropriate manner. Open-ended questions (e.g., "Tell me what happened") are best. Some children need more directed questioning (e.g., "How did you get that bruise?"); others need multiple choice questions. Leading questions (e.g., "Did your daddy hit you?") must be avoided.
- A thorough physical examination is necessary.
- Careful documentation of the history and physical is essential. Verbatim quotes are valuable, including the question that prompted the response. Photographs are helpful.
- For abuse: What is the evidence for concluding abuse? Have other diagnoses been ruled out? What is the likely mechanism of the injury? When did the injury likely occur?
- For neglect: Do the circumstances indicate that the child's needs have not been adequately met? Is there evidence of actual harm? Is there evidence of potential harm and on what basis? What is the nature of the neglect? Is there a pattern of neglect?
- Are there indications of other forms of maltreatment? Has there been prior CPS involvement?
- A child's safety is a paramount concern. What is the risk of imminent harm, and of what severity?
- What is contributing to the maltreatment? Consider the categories described in the section on etiology.
- What strengths/resources are there? This is as important as identifying problems.
- What interventions have been tried, with what results? Knowing the nature of these interventions can be useful, including from the parent's perspective.
- What is the prognosis? Is the family motivated to improve the circumstances and accept help, or resistant? Are suitable resources, formal and informal, available?
- Are there other children in the home who should be assessed for maltreatment?

GENERAL PRINCIPLES FOR ADDRESSING CHILD MALTREATMENT

The circumstances surrounding each child and/or incident of suspected abuse or neglect may be complex and highly variable, precluding specific steps. The following are general principles.

- Treat any medical problems.
- Help ensure the child's safety, often in conjunction with CPS; this is a priority.
- Convey concerns of maltreatment to parents, kindly but forthrightly. Avoid blaming. It is natural to feel anger or pain towards parents of maltreated children, but they need support and deserve respect.
- Have a means of addressing the difficult emotions child maltreatment can evoke in us.
- Be empathic and state interest in helping, or suggest another pediatrician.
- Know your national and state laws and/or local CPS policies on reporting child maltreatment. In the United States, the legal threshold for reporting is typically "reason to believe"; one does not need to be certain. Physical abuse and moderate to severe neglect warrant a report. In less-severe neglect, less-intrusive interventions may be an appropriate initial response. For example, if an infant's mild failure to thrive is a result of an error in mixing the formula, parent education and perhaps a visiting nurse should be tried. In contrast, severe failure to thrive may require hospitalization, and if the contributing factors are particularly serious (e.g., a psychotic mother), out-of-home placement may be needed. CPS can assess the home environment, providing valuable insights.
- Reporting child maltreatment is never easy. Parental inadequacy or culpability is at least implicit, and parents may express considerable anger. Child healthcare professionals should supportively inform families directly of the report; it can be explained as an effort to clarify the situation and provide help, as well as a professional (and legal) responsibility. Explaining what the ensuing process is likely to entail (e.g., a visit from a CPS worker and sometimes a police officer) may ease a parent's anxiety. Parents are frequently concerned that they might lose their child. Child healthcare professionals can cautiously reassure parents that CPS is responsible for helping children and families and that, in most instances, children remain with their parents. Even when CPS does not accept a report or when a report is not substantiated, they may offer voluntary supportive services such as food, shelter, homemaker services, and child care. Child healthcare professionals can be a useful liaison between the family and the public agencies, and should try to remain involved after reporting to CPS.
- Help address contributory factors, prioritizing those most important and amenable to being remedied. Concrete needs should not be overlooked; accessing nutrition programs, obtaining health insurance, enrolling children in preschool programs, and help finding safe housing can make a valuable difference. Parents may need their own problems addressed to enable them to adequately care for their children.
- Establish specific objectives (e.g., no hitting, diabetes will be adequately controlled), with measurable outcomes (e.g., urine dipsticks, hemoglobin A_{1c}). Similarly, advice should be specific and limited to a few reasonable steps. A written contract can be very helpful.
- Engage the family in developing the plan, solicit their input and agreement.
- Build on strengths; there are always some. These provide a valuable way to engage parents.
- Encourage informal supports (e.g., family, friends; invite fathers to office visits). This is where most people get their support, not from professionals. Consider support available through a family's religious affiliation.
- Consider children's specific needs. Too often, maltreated children do not receive direct services.
- Be knowledgeable about community resources, and facilitate appropriate referrals.
- Provide support, follow-up, review of progress, and adjust the plan if needed.
- Recognize that maltreatment often requires long-term intervention with ongoing support and monitoring.

OUTCOMES OF CHILD MALTREATMENT

Child maltreatment often has significant short- and long-term medical, mental health, and social sequelae. Physically abused children are at risk for many problems, including conduct disorders, aggressive behavior, decreased cognitive functioning, and poor academic performance. Neglect is similarly associated with many potential problems. Even if a maltreated child appears to be functioning well, healthcare professionals and parents need to be sensitive to the possibility of later problems. Maltreatment is associated with increased risk in adulthood for several health risk behaviors and physical and mental health problems. Maltreated children are at risk for becoming abusive parents. The neurobiologic effects of child abuse and neglect on the developing brain may partly explain some of these sequelae.

Some children appear to be resilient and may not exhibit sequelae of maltreatment, perhaps owing to protective factors or interventions. The benefits of intervention have been found in even the most severely neglected children, such as those from Romanian orphanages, who were adopted—the earlier the better.

PREVENTION OF CHILD ABUSE AND NEGLECT

An important aspect of prevention is that many of the efforts to strengthen families and support parents should promote children's health, development, and safety, as well as prevent child abuse and neglect. Medical responses to child maltreatment have typically occurred after the fact; preventing the problem is preferable. Child healthcare professionals can help in several ways. An ongoing relationship offers opportunities to develop trust and knowledge of a family's

circumstances. Astute observation of parent–child interactions can reveal useful information.

Parent and child education regarding medical conditions helps to ensure implementation of the treatment plan and to prevent neglect. Possible barriers to treatment should be addressed. Practical strategies such as writing down the plan can help. In addition, anticipatory guidance may help with child rearing, diminishing the risk of maltreatment. Hospital-based programs that educate parents about infant crying and the risks of shaking the infant may help prevent AHT.

Screening for major psychosocial risk factors for maltreatment (depression, substance abuse, intimate partner violence, major stress), and helping address identified problems, often via referrals, may help prevent maltreatment. The primary care focus on prevention offers excellent opportunities to screen briefly for psychosocial problems. The traditional organ system–focused review of systems can be expanded to probe areas such as feelings about the child, the parent's own functioning, possible depression, substance abuse, intimate partner violence, disciplinary approaches, stressors, and supports. The Safe Environment for Every Kid (SEEK) model offers a promising approach for pediatric primary care to identify and help address prevalent psychosocial problems. So doing can strengthen families, support parents, promote children's health, development and safety, and, help prevent child maltreatment.

Obtaining information directly from children or youth is also important, especially given that separate interviews with teens have become the norm. Any concerns identified on such screens require at least brief assessment and initial management, which may lead to a referral for further evaluation and treatment. More frequent office visits can be scheduled for support and counseling while monitoring the situation. Other key family members (e.g., fathers) might be invited to participate, thereby encouraging informal support. Practices might arrange parent groups through which problems and solutions are shared.

Advocacy

Child health professionals can assist in understanding what contributed to the child's maltreatment. When advocating for the best interest of the child and family, addressing risk factors at the individual, family, and community levels is optimal. At the individual level, an example of advocating on behalf of a child is explaining to a parent that an active toddler is behaving normally and not intentionally challenging the parent. Encouraging a mother to seek help dealing with a violent spouse, saying for example, "You and your life are very important," asking about substance abuse and helping parents obtain health insurance for their children are all forms of advocacy. Child abuse can and does occur even in families in which one spouse does not support or condone the abusive behavior (Fig. 40-10).

Efforts to improve family functioning, such as encouraging fathers' involvement in child care are also examples of advocacy. Remaining involved after a report to CPS and helping ensure appropriate services are provided is advocacy as well. In the community, child health professionals can be influential advocates for maximizing resources devoted to children and families. These include parenting programs, services for abused women and children, and recreational facilities. Finally, child health professionals can play an important role in advocating for policies and programs at the local, state, and national levels to benefit children and families. Child maltreatment is a complex problem that has no easy solutions.

40.1 Sexual Abuse

Wendy G. Lane and Howard Dubowitz

See also Chapter 119, Adolescent Rape.

Approximately 25% of girls and 10% of boys in the United States will be sexually abused at some point during their childhood. Rates vary across the globe, with children in some countries experiencing even higher rates. Whether children and families share this information with their pediatrician will depend, in large part, on the pediatrician's comfort with and openness to discussing possible sexual abuse with families.

Pediatricians may play a number of different roles in addressing sexual abuse, including identification, reporting to CPS, testing for and treating sexually transmitted infections, and providing support and reassurance to children and families. Pediatricians may also play a role in the prevention of sexual abuse by advising parents and children about ways to help keep safe from sexual abuse. In many jurisdictions throughout the United States, general pediatricians will play a triage role, with the definitive medical evaluation conducted by a child abuse specialist.

DEFINITION

Sexual abuse may be defined as any sexual behavior or action toward a child that is unwanted or exploitative. Some legal definitions distinguish sexual abuse from sexual assault; the former being committed by a caregiver or household member, and the latter being committed by someone with a noncustodial relationship or no relationship with the child. For this chapter, the term *sexual abuse* encompasses both abuse and assault. Sexual abuse does *not* have to involve direct touching or contact by the perpetrator. Showing pornography to a child, filming or photographing a child in sexually explicit poses, and encouraging or forcing one child to perform sex acts on another also constitute sexual abuse.

PRESENTATION OF SEXUAL ABUSE

Caregivers may become concerned about the possibility of sexual abuse when children exhibit sexually explicit behavior. This behavior includes that which is outside the norm for a child's age and developmental level. For preschool and school-age children, sexually explicit behavior may include compulsive masturbation, attempting to perform sex acts on adults or other children, or asking adults or children to perform sex acts on them. Teenagers may become sexually promiscuous and even engage in prostitution. Older children and teenagers may respond by sexually abusing younger children. It is important to recognize that this behavior could also result from accidental exposure (e.g., the child who enters his parent's bedroom at night to find his parents having sex), or from neglect (e.g., watching pornographic movies where a child can see them).

Children who have been sexually abused sometimes provide a clear, spontaneous disclosure to a trusted adult. Often the signs of sexual abuse are much more subtle. For some children, behavioral changes are the first indication that something is amiss. Nonspecific behavior changes such as social withdrawal, acting out, increased clinginess or fearfulness, distractibility, and learning difficulties may be attributed to a variety of life changes or stressors. Regression in developmental milestones, including new-onset bedwetting or encopresis (see Chapter 23), is another behavior that caregivers may overlook as an indicator of sexual abuse. Teenagers may respond by becoming depressed, experimenting with drugs or alcohol, or running away from home. Because nonspecific symptoms are very common among children who have been sexually abused, it should nearly always be included in one's differential diagnosis of child behavior changes.

Some children may not exhibit behavioral changes or provide any other indication that something is wrong. For these children, sexual abuse may be discovered when another person witnesses the abuse or discovers evidence such as sexually explicit photographs or videos. Pregnancy may be another way that sexual abuse is identified. There are also children, with and without symptoms, who will not be identified at any point during their childhood.

THE ROLE OF THE GENERAL PEDIATRICIAN IN THE ASSESSMENT AND MANAGEMENT OF POSSIBLE SEXUAL ABUSE

Before determining where and how a child with suspected sexual abuse is evaluated, it is important to assess for and rule out any medical problems that can be confused with abuse. A number of genital findings may raise concern about abuse but often have alternative explanations. Genital redness in a prepubertal child is more often caused by nonspecific vulvovaginitis, eczema, or infection with staphylococcus, group A streptococcus, *Haemophilus*, *Neisseria*, or yeast. Lichen sclerosis is a less-common cause of redness. Vaginal discharge can be caused by sexually transmitted infections, but also by vaginal foreign body, onset of puberty, or infection with *Salmonella*, *Shigella*, or *Yersinia*. Genital ulcers can be caused by herpes simplex virus and syphilis, but also by Epstein-Barr virus, varicella-zoster, Crohn disease, and Behçet disease. Genital bleeding can be caused by urethral prolapse, vaginal foreign body, accidental trauma, and vaginal tumor.

When other medical conditions are not under consideration, have been ruled out, or are less likely than abuse, the possibility for suspected sexual abuse should be probed (Fig. 40-11). Where and how a child with suspected sexual abuse is evaluated should be determined by how long ago the last incident of abuse likely occurred, and whether the child is prepubertal or postpubertal. For the prepubertal child, if abuse has occurred in the previous 72 hr, forensic evidence collection (e.g., external genital, vaginal, anal, and oral swabs, sometimes referred to as a "rape kit") is often indicated, and the child should be referred to a site equipped to collect forensic evidence. Depending on the jurisdiction, this site may be an emergency department, a child advocacy center, or an outpatient clinic. If the last incident of abuse occurred more than 72 hr prior, the likelihood of recovering forensic evidence is extremely low, and forensic evidence collection is not necessary. For postpubertal females, many experts recommend forensic evidence collection up to 120 hr following the abuse—the same time limit as for adult women. The extended time frame is justified because some studies have demonstrated that semen can remain in the postpubertal vaginal vault for more than 72 hr.

The referral site may be different when the child does not present until after the cutoff for an acute exam. Because emergency departments may not have a child abuse expert, and can be busy, noisy, and lacking in privacy, examination at an alternate location such as a child

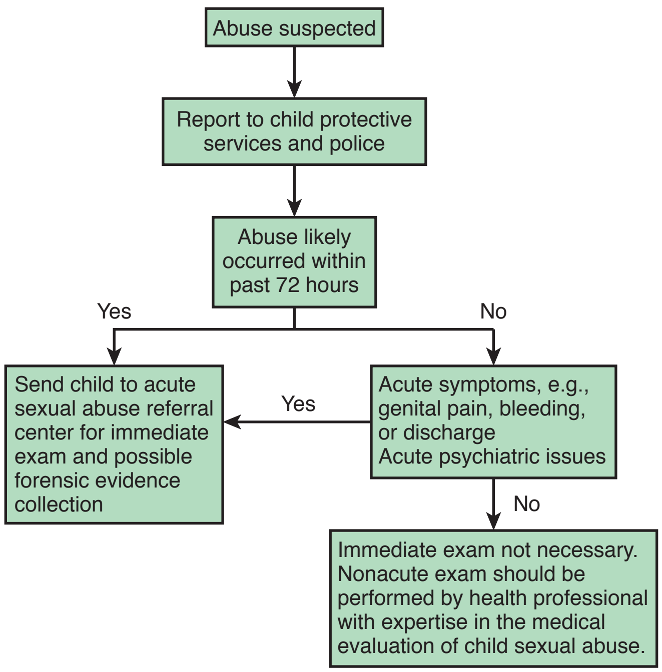

Figure 40-11 Triage protocol for children with suspected sexual abuse.

advocacy center or outpatient clinic is recommended. If the exam is not urgent, waiting until the next morning is recommended because it is easier to interview and examine a child who is not tired and cranky. Referring physicians should be familiar with the triage procedures in their communities, including the referral sites for both acute and chronic exams, and whether there are separate referral sites for prepubertal and postpubertal children.

Children with suspected sexual abuse may present to the pediatrician's office with a clear disclosure of abuse or more subtle indicators. In this situation, a private, brief conversation between pediatrician and child can provide an opportunity for the child to speak in the child's own words without the parent speaking for the child. Doing this may be especially important when the caregiver does not believe the child, or is unwilling or unable to offer emotional support and protection. Telling caregivers that a private conversation is part of the routine assessment for the child's concerns can help comfort a hesitant parent.

When speaking with the child, experts recommend establishing rapport by starting with general and open-ended questions; for example: "Who lives at home?" and "What are your favorite things to do?" Questions about sexual abuse should be nonleading. A pediatrician should explain that sometimes children are hurt or bothered by others, and that the physician wonders whether that might have happened to the child. Open-ended questions, such as "Can you tell me more about that?" allow the child to provide additional information and clarification in the child's own words. It is *not* necessary to obtain extensive information about what happened because the child will usually have a forensic interview once a report is made to CPS and an investigation begins. Very young children and those with developmental delay may lack the verbal skills to describe what happened. In this situation, the caregiver's history may provide enough information to warrant a report to CPS without interviewing the child.

All 50 U.S. states (and a growing number of other nations) mandate that professionals report suspected maltreatment to CPS. The specific criteria for "reason to suspect" are generally not defined by state law. It is clear that reporting does not require certainty that abuse has occurred. Therefore, it may be appropriate to report a child with sexual behavior concerns when no accidental sexual exposure can be identified and the child does not clearly confirm or deny abuse during your conversation with her.

PHYSICAL EXAMINATION OF THE CHILD WITH SUSPECTED SEXUAL ABUSE

Many physicians are unfamiliar with genital anatomy and examination, particularly in the prepubertal child (Figs. 40-12 and 40-13). Because approximately 95% of children who undergo a medical evaluation following sexual abuse have normal exams, the role of the primary care provider is often simply to be able to distinguish a normal exam from findings indicative of common medical concerns or trauma. The absence of physical findings can often be explained by the type of sexual contact that has occurred. Abusive acts such as fondling or even

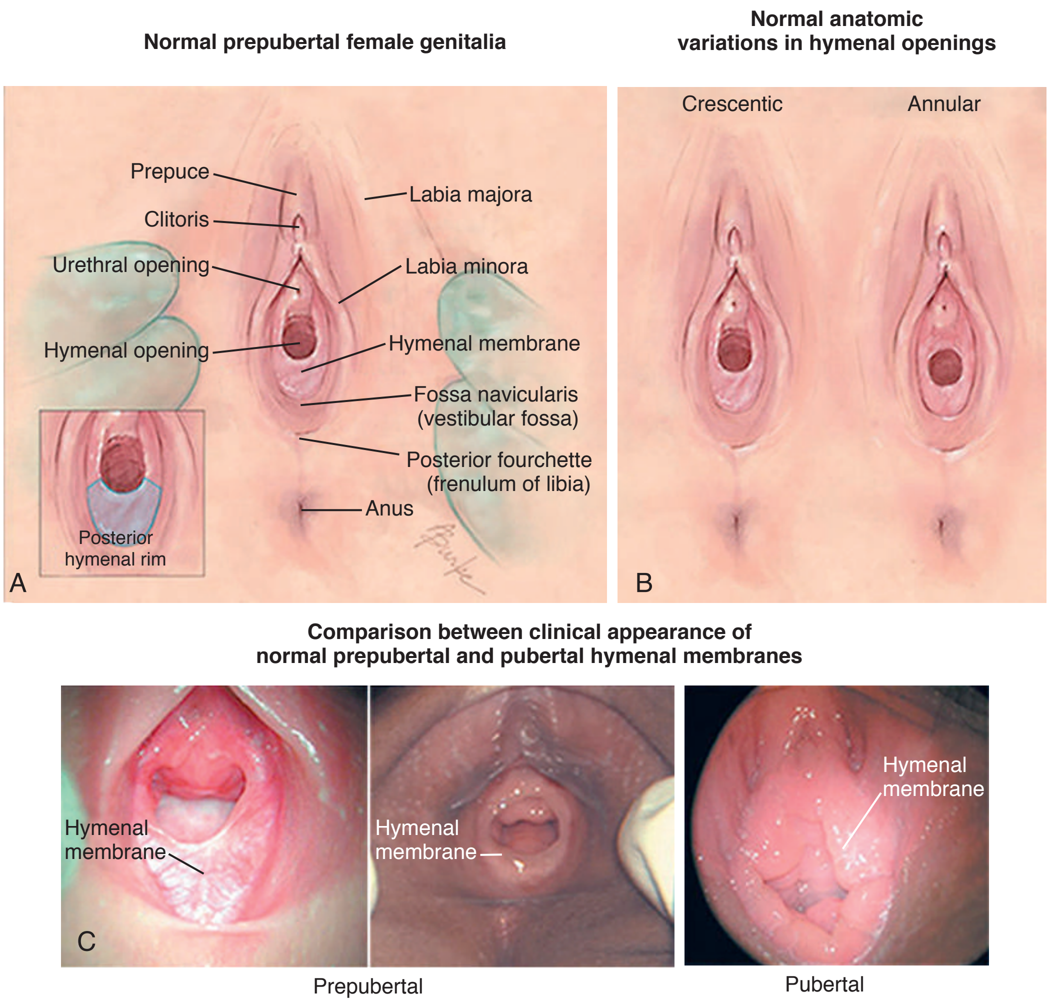

Figure 40-12 Female prepubertal genital anatomy. **A,** Inset shows the region defined as the posterior hymenal rim, between the 4 o'clock and 8 o'clock positions (*shaded blue*). **B,** There is a range of normal anatomic variations in hymenal openings. Crescentic and annular are two of the most common shapes. **C,** Photographs illustrate the range of normal prepubertal and pubertal hymenal membranes. In most children, the hymen becomes thicker and more redundant during puberty. *(From Berkoff MC, Zolotor AJ, Makoroff KL, et al: Has this prepubertal girl been sexually abused?* JAMA *300:2779-2792, 2008.)*

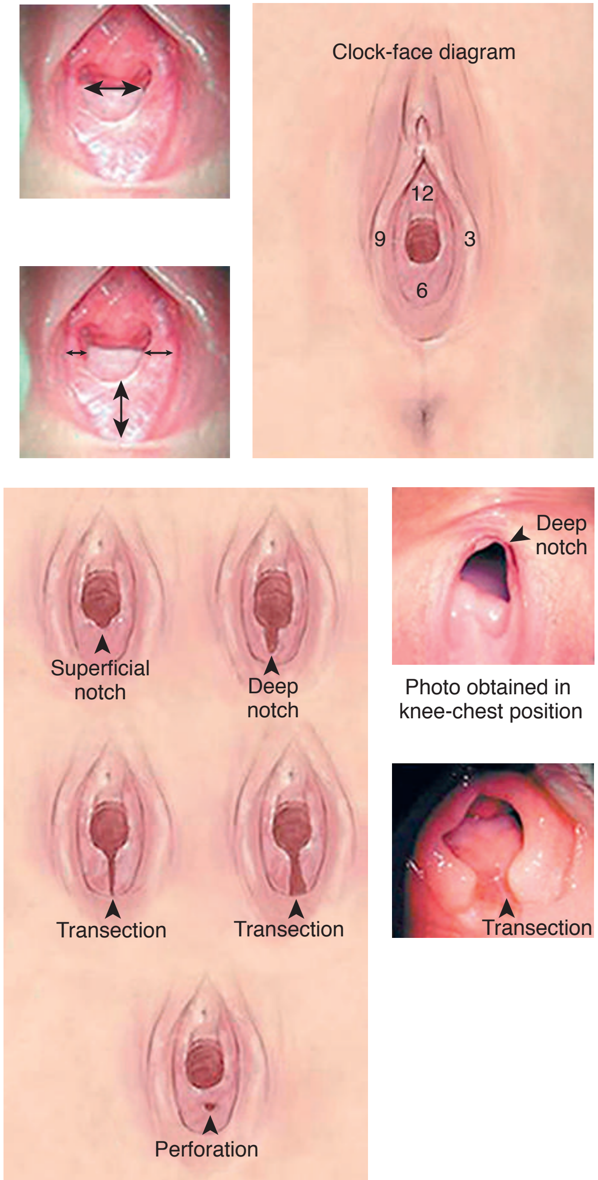

Figure 40-13 **Hymenal membrane characteristics.** When considering the possibility of sexual abuse during an examination, the examiner should document pertinent positive and negative findings. In addition to the clinical signs depicted in the figure, other possible findings include prominent hymenal vessels, bumps, tags, longitudinal intravaginal ridge, external ridge, periurethral bands, or vestibular bands. Perforation of the hymen is not a finding commonly discussed in the literature. *(From Berkoff MC, Zolotor AJ, Makoroff KL, et al: Has this prepubertal girl been sexually abused?* JAMA *300:2779-2792, 2008.)*

digital penetration can occur without causing injury. Many children do not disclose abuse until days, weeks, months, or even years after the abuse has occurred; because genital injuries can heal rapidly, injuries are often completely healed by the time a child presents for medical evaluation. A normal genital exam does not rule out the possibility of abuse, and should not influence the decision to report to CPS.

Even with the high proportion of normal genital exams, there is value in conducting a thorough physical exam. Unsuspected injuries or medical problems, such as labial adhesions, imperforate hymen, or a small urethral prolapse, may be identified. In addition, reassurance about the child's physical health may allay fears and reduce anxiety for the child and family.

Few findings on the genital examination are diagnostic for sexual abuse. In the acute time frame, lacerations or bruising of the labia,

Table 40-5	Situations Involving a High Risk for Transmission of Sexually Transmitted Infections

1. Child has signs or symptoms of STI, including vaginal discharge or pain, genital itching or odor, urinary symptoms, and genital ulcers or lesions.
2. The suspected perpetrator is known to have an STI, or is at high risk for having an STI because of multiple partners, substance abuse, or other reasons.
3. Any other person living in the child's household has an STI.
4. There is evidence of genital, oral, or anal penetration or ejaculation.
5. The patient or parent requests testing.

STI, sexually transmitted infection.

From Centers for Disease Control and Prevention, Workowski KA, Berman SM: Sexually transmitted diseases treatment guidelines, 2010, MMWR Recomm Rep *59(RR-12):1-114, 2010.*

penis, scrotum, perianal tissues, or perineum are indicative of trauma. Likewise, hymenal bruising and lacerations, and perianal lacerations extending deep to the external anal sphincter indicate penetrating trauma. Several nonacute findings are also concerning for sexual abuse. A complete transection of the hymen to the base between the 4 and 8 o'clock positions (i.e., absence of hymenal tissue in the posterior rim) is considered diagnostic for trauma (see Fig. 40-13). For all of these findings, the cause of injury must be elucidated through the child and caregiver history. If there is any concern that the finding may be the result of sexual abuse, CPS should be notified and a medical evaluation should be performed by an experienced child abuse pediatrician.

Testing for sexually transmitted infections is not indicated for all children, but is warranted in the situations described in Table 40-5. Until recently, culture was considered the gold standard for the diagnosis of vaginal gonorrhea (see Chapter 192) and chlamydia (see Chapter 226) infections in children. There is growing evidence that **nucleic acid amplification testing (NAAT)** for gonorrhea and chlamydia by either vaginal swab or urine in prepubertal girls is as (or possibly more) sensitive, than culture. Current guidelines from the Centers for Disease Control and Prevention (CDC) allow for NAAT testing by vaginal swab or urine as an alternative to culture in girls. Because obtaining vaginal swabs can be uncomfortable for prepubertal children, urine testing is preferable. Culture remains the preferred method for testing of rectal and pharyngeal specimens in boys and girls. Little data on the use of urine NAAT testing in prepubertal boys is available. Therefore, the CDC continues to recommend urine or urethral culture for boys. Many child abuse experts perform urine NAAT testing on prepubertal boys because urethral swabs are uncomfortable, and there are good data to support urine NAAT testing in girls. For all NAAT testing in both genders, the child should *not* receive presumptive treatment at the time of testing. Instead, a positive NAAT test should be confirmed by culture or an alternate NAAT test prior to treatment. Because gonorrhea and chlamydia in prepubertal children do not typically cause ascending infection, waiting for a definitive diagnosis before treatment will not increase the risk for pelvic inflammatory disease.

A number of sexually transmitted infections should raise concern for abuse (Table 40-6). In a prepubertal child, a positive culture for gonorrhea beyond the neonatal period, trichomonas beyond 1 yr of age, or chlamydia beyond 3 yr of age indicates that the child has had some contact with infected genital secretions, almost always as a result of sexual abuse. Syphilis (see Chapter 218) and HIV are diagnostic for sexual abuse if other means of transmission have been excluded. Because of the potential for transmission either perinatally or through nonsexual contact, the presence of genital warts has a low specificity for sexual abuse. The possibility of sexual abuse should be considered and addressed with the family, especially in children whose warts first appear beyond 3 yr of age. Type 1 or 2 genital herpes is concerning for sexual abuse, but not diagnostic given other possible routes of

transmission. For both human papillomavirus and herpes simplex virus, the American Academy of Pediatrics recommends reporting to CPS unless perinatal or horizontal transmission is considered likely.

SEXUAL ABUSE PREVENTION

Pediatricians can play a role in the prevention of sexual abuse by educating parents and children about sexual safety at well child visits. During the genital exam the pediatrician can inform the child that only the doctor and select adult caregivers should be permitted to see their "private parts," and that a trusted adult should be told if anyone else attempts to do so. Pediatricians can raise parental awareness that sometimes older kids or adults may try engage in sexual behavior with children. The pediatrician can teach parents how to minimize the opportunity for perpetrators to access children, for example, by limiting 1-adult/1-child situations and being sensitive to any adult's unusual interest in young children. In addition, pediatricians can help parents talk to children about what to do if confronted with a potentially abusive situation. Some examples include telling children to say "no," to leave, and to tell a parent and/or another adult. If abuse does occur, the pediatrician can tell parents how to recognize possible signs and symptoms, and how to reassure the child that she or he was not at fault. Finally, pediatricians can provide parents with suggestions about how to maintain open communication with their children so that these conversations can occur with minimal parent and child discomfort.

40.2 Medical Child Abuse (Factitious Disorder by Proxy, Munchausen Syndrome by Proxy)

Howard Dubowitz and Wendy G. Lane

The term *Munchausen syndrome* is used to describe situations in which adults falsify their own symptoms. In *Munchausen syndrome by proxy*, a parent, typically a mother, simulates or causes disease in her child. Several terms have been suggested to describe this phenomenon: factitious disorder by proxy, pediatric condition falsification, caregiver fabricated illness, and **medical child abuse (MCA)**. In some instances, such as partial suffocation, "child abuse" may be most appropriate.

The core dynamic is that a parent falsely presents a child for medical attention. This may be via fabricating a history, such as reporting seizures that never occurred. A parent may directly cause a child's illness by exposing a child to a toxin, medication, or infectious agent (e.g., injecting stool into an intravenous line). Signs or symptoms may also be manufactured, such as when a parent smothers a child, or alters laboratory samples or temperature measurements. Each of these actions may lead to unnecessary medical care, sometimes including intrusive tests and surgeries. The "problems" often recur repeatedly over several years. In addition to the physical concomitants of testing and treatment, there are potentially serious and lasting social and psychologic sequelae.

Child health professionals are typically misled into thinking that the child really has a medical problem. Parents, sometimes working in a medical field, may be adept at constructing somewhat plausible presentations; a convincing seizure history may be offered, and a normal electroencephalogram cannot fully rule out the possibility of a seizure disorder. Even after extensive testing fails to lead to a diagnosis or treatment proves ineffective, health professionals may think they are confronting a "new or rare disease." Unwittingly, this can lead to continued testing and interventions, thus perpetuating the MCA. Pediatricians generally rely on and trust parents to provide an accurate history. As with other forms of child maltreatment, accurate diagnosis of MCA requires that the pediatrician maintain a healthy skepticism under certain circumstances.

CLINICAL MANIFESTATIONS

As with other forms of child abuse, the presentation of MCA may vary in nature and severity. Consideration of MCA should be triggered when the reported symptoms are repeatedly noted by only one parent, appropriate testing fails to confirm a diagnosis, and seemingly appropriate treatment is ineffective. The child's symptoms, their course, or the response to treatment may be incompatible with any recognized disease. Preverbal children are usually involved, although older children may be convinced by parents that they have a particular problem and become dependent on the increased attention; this may lead to feigning symptoms.

Symptoms in young children are mostly associated with proximity of the offending caregiver to the child. The mother may present as a devoted or even model parent who forms close relationships with members of the healthcare team. While appearing very interested in her child's condition, she may be relatively distant emotionally. She may have a history of Munchausen syndrome, though not necessarily diagnosed as such. **Bleeding** is a particularly common presentation. This may be caused by adding dyes to samples, adding blood (e.g., from the mother) to the child's sample, or giving the child an anticoagulant (e.g., warfarin).

Seizures are a common manifestation, with a history easy to fabricate, and the difficulty of excluding the problem based on testing. A parent may report that another physician diagnosed seizures, and the myth may be continued if there is no effort to confirm the basis for the "diagnosis." Alternatively, seizures may be induced by toxins, medications (e.g., insulin), water, or salts. Physicians need to be familiar with the substances available to families and the possible consequences of exposure.

Apnea is another common presentation. The observation may be falsified or created by partial suffocation. A history of a sibling with the same problem, perhaps dying from it, should be cause for concern. Parents of children hospitalized for apparent life-threatening events have been videotaped attempting to suffocate their child while in the hospital.

Gastrointestinal signs or symptoms are another common manifestation. Forced ingestion of medications such as ipecac may cause chronic vomiting, or laxatives may cause diarrhea.

Recurrent sepsis may be caused by infectious agents being administered; intravenous lines during hospitalization may provide a convenient portal. Urine and blood samples may be contaminated with foreign material, blood or stool.

DIAGNOSIS

In assessing possible MCA, several explanations should be considered in addition to a true medical problem. Some parents may be extremely anxious and genuinely concerned about possible problems. There may be many reasons underpinning this anxiety, such as a personality trait, the death of neighbor's child, or something read on the Internet. Alternatively, parents may believe something told to them by a trusted physician despite subsequent evidence to the contrary and efforts to correct the earlier misdiagnosis. Physicians may unwittingly contribute to a parent's belief that a real problem exists by, perhaps reasonably, persistently pursuing a medical diagnosis. There is a need to discern commonly used hyperbole (e.g., exaggerating the height of the fever) in order to evoke concern and perhaps justify a visit to an emergency department. In the end, a diagnosis of MCA rests on clear evidence of a child repeatedly being subjected to unnecessary medical tests and treatment, primarily stemming from a parent's actions. Determining the parent's underlying psychopathology is the responsibility of mental health professionals.

Once MCA is suspected, gathering and reviewing **all** the child's medical records is an onerous but critical first step. It is often important to confer with other treating physicians about what specifically was conveyed to the family. A mother may report that the child's physician insisted that a certain test be done when it may be the mother instead who demanded the test. It is also necessary to confirm the basis for a given diagnosis, rather than simply accepting a parent's account.

Pediatricians may face the dilemma of when to accept that all plausible diagnoses have been reasonably ruled out, the circumstances fit MCA, and further testing and treatment should cease. The likelihood of MCA must be balanced with concerns about possibly missing an important diagnosis. Consultation with a pediatrician expert in child abuse is recommended. In evaluating possible MCA, specimens should be carefully collected, with no opportunity for tampering with them. Similarly, temperature measurements should be closely observed.

Depending on the severity and complexity, hospitalization may be needed for careful observation to help make the diagnosis. In some instances, such as repeated apparent life-threatening events, covert video surveillance accompanied by close monitoring (to rapidly intervene in case a parent attempts to suffocate a child) can be valuable. It is important that there be close coordination among hospital staff, especially as some may side with the mother and resent even the possibility of MCA being raised. Parents should not be informed of the evaluation for MCA until the diagnosis is made. Doing so could naturally influence their behavior and jeopardize establishing the diagnosis. All steps in making the diagnosis and all pertinent information should be very carefully documented, perhaps using a "shadow" chart that the parent does not have access to.

TREATMENT

Once the diagnosis is established, the treatment plan should be worked out by the medical team and CPS; it may require out-of-home placement and should include mental healthcare for the offending parent as well as for older affected children. Further medical care should be carefully organized and coordinated by one primary care provider. CPS should be encouraged to meet with the family only after the medical team has informed the offending parent of the diagnosis; their earlier involvement may hamper the evaluation. Parents often respond with resistance, denial, and threats. It may be prudent to have hospital security in the vicinity.

Chapter 41

Failure to Thrive

Heather S. McLean and David T. Price

Failure to thrive (FTT) results from inadequate usable calories necessary for a child's metabolic and growth demands. No single set of growth parameters provides the criteria for a universal definition. FTT has classically been grouped into organic and nonorganic types; this construct is outmoded and not useful to clinicians seeking to address underlying causes, which are often multifactorial. Many would consider a weight for height ratio less than 2 SD (or <3 or 5 percentile) for age and gender diagnostic of FTT; others would use weight crossing 2 major percentiles on the growth curve. Patients with FTT may either have growth deceleration, faltering growth, or even weight loss.

A biopsychosocial model helps explain the complex interplay between even minor illnesses, the mental health of caregivers, and the home environment. The interaction between the child and parent is often complex; parent expectations of child behavior and the actual temperament of the infant create a transactional model where at times it is often difficult to separate cause and effect (action and reaction). The infant brings to this model an innate temperament with behavioral domains such as activity, adaptability, distractibility, response to new stimuli, and intensity of responses. Some infants are "easy babies," whereas others are more "difficult." These behaviors may interact with different maternal expectations or understanding of child behavior. Additional maternal contributions to this model may include postpartum depression, and the mother's own history of abuse or neglect as a child, as well as home environmental issues such as family stress, poor social/emotional support, poverty, and a chaotic lifestyle. In addition, many medical causes of FTT are associated with these same psychosocial risk factors; both need to be addressed in the management of FTT.

CLINICAL MANIFESTATIONS

Inadequate weight for corrected age, weight for height, and body mass index, as well as failure to gain adequate weight over a period of time, help define FTT (see Chapter 15). Growth parameters should be measured serially and plotted on growth charts appropriate for the child's sex, age, and, if preterm, postconceptual age. Growth charts are also available for some known chromosomal abnormalities, such as Down syndrome and Turner syndrome (see Chapter 81).

ETIOLOGY AND DIAGNOSIS

The causes of insufficient growth include (1) failure of the child to ingest and utilize sufficient calories, (2) malabsorption, and (3) increased metabolic demands. Focus the diagnostic approach on the cause of undernutrition. History, physical examination, and observation of the parent–child interaction in the clinical or home environment usually suggest the most likely etiologies and thus direct appropriate workup and management. A complete history should include a detailed nutritional, family, and prenatal history; documentation of child and caregiver interaction, the quantity, quality and frequency of meals, and further information regarding the onset of the growth failure (Table 41-1).

Many children with FTT will be solely categorized because of deprivation and/or psychological problems and rarely just because of child neglect. These families often share risk factors with neglect, such as poverty, social isolation, and caregiver mental health issues.

The medical causes of FTT may involve every organ system. The clinician may approach the diagnosis in terms of cause (Tables 41-2 and 41-3) or signs and symptoms (Table 41-4). The onset of growth deficiency can indicate a cause, such as the introduction of gluten into the diet of a child with celiac disease or a coincidental psychosocial event. A chromosomal abnormality, intrauterine infection, or

Table 41-4 Approach to Failure to Thrive Based on Signs and Symptoms

HISTORY/PHYSICAL EXAMINATION	DIAGNOSTIC CONSIDERATION
Spitting, vomiting, food refusal	Gastroesophageal reflux, chronic tonsillitis, food allergies, eosinophilic esophagitis
Diarrhea, fatty stools	Malabsorption, intestinal parasites, milk protein intolerance, pancreatic insufficiency, celiac disease, immunodeficiency, inflammatory bowel disease
Snoring, mouth breathing, enlarged tonsils	Adenoid hypertrophy, obstructive sleep apnea
Recurrent wheezing, pulmonary infections	Asthma, aspiration, food allergy, cystic fibrosis, immunodeficiency
Recurrent infections	HIV or congenital immunodeficiency diseases, anatomic defects
Travel to/from developing countries	Parasitic or bacterial infections of the gastrointestinal tract

teratogen exposure should be considered in a child with symmetric growth failure since birth. Investigation for metabolic disorders should be considered in children with FTT accompanied by 1 of the following factors: history of acute, severe, and potentially life-threatening symptoms, recurrent vomiting, liver dysfunction, neurologic symptoms, cardiomyopathy and myopathy, impairment of special senses, renal symptoms, or distinct dysmorphic features and/or organomegaly.

The physical examination should focus on identifying chronic illnesses, recognizing syndromes that may alter growth, and documenting the effects of malnutrition (Table 41-5).

Laboratory evaluation of children with FTT should be judicious and based on findings from the history and physical. Obtaining the state's newborn screening results, a complete blood count, and urinalysis represent a reasonable initial screen. Testing for celiac disease is indicated in children if the poor growth coincided with gluten exposure (see Chapter 338).

TREATMENT

Treatment requires a multidisciplinary approach and an understanding of all the medical and psychosocial elements that contribute to a child's

Table 41-5	Approach to Physical Examination
Vital signs	Blood pressure, if over 2 yr, temperature, pulse, respirations, oxygen saturation, anthropometry (growth percentiles, body mass index)
General appearance	Activity, affect, posture
Skin	Hygiene, rashes, trauma (bruises, burns, scars)
Head	Hair whorls, color and pluckability of hair, occipital alopecia, fontanel size and patency, frontal bossing, sutures, shape, facial dysmorphisms, philtrum
Eyes	Ptosis, strabismus, fundoscopic examination where possible, palpebral fissures, conjunctival pallor, icterus, cataracts
Ears	External form, rotation, tympanic membranes
Mouth, nose, throat	Thinness of lip, hydration, dental eruption and hygiene caries, glossitis, cheilosis, gum bleeding, marked tonsillar enlargement
Neck	Hairline, masses, lymphadenopathy

Genitalia	Malformations, hygiene, trauma
Rectum	Fissures, trauma, hemorrhoids
Extremities	Edema, dysmorphisms, rachitic changes, nails and nail beds
Neurologic	Cranial nerves, reflexes, tone, retention of primitive reflexes, quality of voluntary movement

From American Academy of Pediatrics Committee on Nutrition: Failure to thrive. In Kleinman RE, Greer FR, editors: Pediatric nutrition, *ed 7, Elk Grove Village, IL, 2014, American Academy of Pediatrics, Tab 27-3.*

growth: a child's health and nutritional status, family issues, and the parent–child interaction. An appropriate feeding atmosphere at home is important for all children with FTT.

Indications for hospitalization include severe malnutrition or failure of outpatient management. If a child requiring hospitalization has not responded after 2-3 mo of outpatient management, a specialized, multidisciplinary inpatient assessment should be considered. Inpatient care may include further diagnostic and laboratory evaluation, an assessment and implementation of adequate nutrition, and evaluation of the parent–child feeding interaction.

Children with severe malnutrition must be refed carefully, with an incremental increase in calories to avoid refeeding syndrome (see Chapter 46). The type of caloric supplementation is based on the severity of FTT and the underlying medical condition. The response to feeding depends on the specific diagnosis, medical treatment, and severity of FTT. Minimal catch-up growth should generally be 2-3 times the average weight gain for corrected age. Multivitamin supplementation should be given to all children with FTT to meet the recommended dietary allowance, because these children commonly have iron, zinc, and vitamin D deficiencies, as well as increased micronutrient demands with catch-up growth.

Therapy for the psychosocial factors should be specific for the underlying issue (maternal depression, insufficient funds for food). In addition, parent education should focus on what is normal infant development and correcting any parental misconceptions about feeding and temperament, as well as learning the infant cues for hunger, satiety, and sleep. Some children who develop feeding aversion behaviors will require treatment by a specialized feeding team. If abuse or purposeful neglect is a concern, the family should be referred to the child protective service team.

PROGNOSIS
